A RECOMMENDATION

The following paragraph, which speaks for itself, is taken from "An Outpost in Papua," by Arthur Kent Chignell, Priest of the New Guinea Mission —

"Rummaging in the Sydney book-shops ... I discovered and bought for ninepence, a secondhand copy of a little book that had been issued only two years before 'THE MAINTENANCE OF HEALTH IN THE TROPICS' written by W J Simpson, M.D and published under the auspices of the London School of Tropical Medicine by John Bale Sons and Danielsson of Great Titchfield Street in London. I give the details fully not only because that book was the very best ninepenny-worth I ever bought, but because a copy should come to New Guinea with everyone who enters the country More than that and because a book is but a lifeless thing until it is read and understood, it would be very well if every volunteer for the New Guinea Mission could be examined as to its contents before he is accepted and catechized as to his willingness to live up to its teaching before he is allowed to sail."

A new edition of the above-mentioned book, thoroughly revised and brought up to date, has recently been published, Price 3s. 6d. net, post free 3s 10d., and can be obtained from the Publishers

JOHN BALE, SONS & DANIELSSON, LTD.,

IE ANIMAL PARASITES OF MAN. By H B FANTHAM, M A Cantab, J W W STEPHENS, M.D Cantab, and F V THEOBALD, M A Cantab Royal 8vo Cloth Pp 932 423 Illustrations 45s net, postage 9d inland

The account of the worms by Professor Stephens is exceptionally well illustrated and full of detail. The whole subject is ating in its complexity and full of biological problems We should also realise that a full knowledge of the bionomics of a parasite the only possible basis for prophylaxis, personal or racial .... The adapter of the section on Arthropods is known as an authority on the fication of the mosquitoes, and probably he is at his best when dealing with questions of pure systematics "—*The British Medical Journal* "The section on protozoa by Fantham may be looked upon as the most complete and satisfactory description of the group at present in print h increased in value by the number and clearness of the illustrations The whole work is of great value placing before the student the important facts relating to so wide a field of natural history which are rapidly increasing in amount and importance Readers are to be ratulated on having so much information gathered together in one volume for their use "—*Journal of the Royal Naval Medical Service.*

The volume is divided up into three main sections dealing with the protozoa, helminthes and arthropoda Dr H B Fantham a clear and exhaustive account of all those protozoa known to be parasitic to man. The helminthological section is dealt with by J W W Stephens and in his hands the subject is most ably treated Prof F V Theobald presents the subject of the arthropoda in hion which makes it useful both to the student of medical entomology and to the practical sanitarian. Mention should be made e excellent figures which illustrate the volume throughout."—*The Lancet*

JOHN BALE, SONS & DANIELSSON, LTD.

THE ANIMAL PARASITES OF MAN. By H B FANTHAM M A Cantab, J W W STEPHENS, M.D Cantab and F V THEOBALD, M A. Cantab Royal 8vo Cloth Pp 932 423 Illustrations 45s net, postage 9d inland

The account of the worms by Professor Stephens ...... is exceptionally well illustrated and full of detail .... The whole subject is fascinating in its complexity and full of biological problems ..... We should also realise that a full knowledge of the bionomics of a parasite forms the only possible basis for prophylaxis, personal or racial. ..... The adapter of the section on Arthropods is known as an authority on the classification of the mosquitoes and probably he is at his best when dealing with questions of pure systematics."—*The British Medical Journal.*

"The section on protozoa by Fantham may be looked upon as the most complete and satisfactory description of the group at present in print, much increased in value by the number and clearness of the illustrations ... The whole work is of great value, placing before the student the most important facts relating to so wide a field of natural history which are rapidly increasing in amount and importance. Readers are to be congratulated on having so much information gathered together in one volume for their use."—*Journal of the Royal Naval Medical Service.*

"The volume is divided up into three main sections dealing with the protozoa, helminthes and arthropoda. .. Dr H B Fantham gives a clear and exhaustive account of all those protozoa known to be parasitic to man. The helminthological section is dealt with by Prof. J W W Stephens and in his hands the subject is most ably treated. ... Prof F V Theobald presents the subject of the arthropoda in a fashion which makes it useful both to the student of medical entomology and to the practical sanitarian ..... Mention should be made of the excellent figures which illustrate the volume throughout."—*The Lancet*

Clinical Surgical Diagnosis for Students and Practitioners.
Containing a Chapter on "Some General Diagnostic Problems in connection with the Military Surgery of the Limbs" By PROFESSOR F DE QUERVAIN Director of the Surgical Clinic University of Basle Translated by J SNOWMAN M D 862 pp, with 604 Illustrations and 5 Coloured Plates Second English Edition. Royal 8vo Price 35s net. Postage inland 7d., abroad 2s
The BRITISH MEDICAL JOURNAL says "We do not know of any better book of its kind
We have never yet seen such a uniformly beautiful collection of pictures of surgical conditions"
A book which we think might well be in the hands, not only of practitioners of medicine in general, but also in those of teachers of surgery"

Delivered before the Royal College of Physicians of London on Nov 7th 1916

By H R DEAN, M D Oxon, F R C P Lond,
PROFESSOR OF PATHOLOGY UNIVERSITY OF MANCHESTER.

MR. PRESIDENT AND GENTLEMEN,—The serum reactions are those which take place between an antigen and its homologous antiserum Of the chemical nature of antigens we have no certain knowledge Examples are bacteria and their products red cells and blood serum when injected into an animal of different species Substances capable of acting as antigens appear to be attached to protein matter and have not as yet been isolated in a pure state Attempts have been made to show that antigens are of a lipoid nature Antigen-containing substances have been extracted with alcohol and ether, and the material obtained after evaporation of the solvent has been injected into animals (Bang and Forssman, 1906, and others) The results obtained have not been conclusive (Ritchie and Miller, 1913) In this connexion it must be remembered that antigens are active in very small amounts, and that an ethereal solution of lipoids, although apparently perfectly clear, may well contain minute fragments of protein matter in suspension Moreover, substances not usually soluble in fat solvents may be dissolved or taken up as a very fine suspension in the presence of lecithin. A chloroform solution of lecithin is able to take up or dissolve such substances as cobra venom, trypsin rennet and even oxide of iron In no case so far as I am aware, has the injection of a pure substance of well defined chemical constitution been followed by the formation of antibodies Our definition of antigen is a substance the introduction of which into the animal body is followed by the formation of a specific antibody

It is usually held (Pick, 1902) that the antibodies are for the greater part precipitated with the globulins of the serum, with the pseudoglobulin fraction in the case of the horse, with the euglobulin fraction in the case of the goat Moreover an increase in the globulins of the serum during the process of immunisation has, on several occasions, been observed It is however, probable that euglobulin and pseudoglobulin merely represent different phases of physical aggregation of their constituent particles, and the difference between even albumin and globulin may be of a physical rather than chemical nature From this point of view the fact that the greater part of the antibody in a serum is precipitated with any particular fraction of globulin yields no information as to the chemical nature of the actual antibody As a matter of fact it was shown by Ledingham (1907) that the ratio of distribution of antitoxin among the various serum proteins—euglobulin pseudoglobulin and albumin—differed considerably at different stages of the process of immunisation We may suppose that the process of immunisation is accompanied by a disturbance of the physical state of the serum proteins and the regrouping of protein molecules may lead to an increase in the globulin fraction

As to the chemical nature of antigen and antibody we are in complete ignorance When however antigen is mixed with antibody a reaction takes place and the occurrence of this reaction can be shown by certain phenomena known as the serum reactions. These reactions are 1 *The precipitation reaction.* When a normal serum or a bacterial extract is mixed with its homologous antiserum a precipitate is formed 2. *The agglutination reaction* When a suspension of red blood corpuscles or bacteria is mixed with homologous antiserum the bacteria or cells are agglutinated to form clumps 3 *Lysis* When red corpuscles or bacteria are mixed with antiserum or complement the cells are dissolved, or at any rate some change takes place which leads to the escape of the intracellular contents 4 *Complement fixation* When antigen is mixed with antiserum and complement, the complement is used up and if subsequently there be added a mixture of red blood corpuscles and homologous antiserum the fixation of the complement can be demonstrated by the absence of hæmolysis 5 *The opsonic reaction* If red cells or bacteria are treated with antiserum the cells or bacteria are so altered that they are more readily ingested by phagocytes This reaction is more marked in the presence of complement

THEORIES IN EXPLANATION OF THE SERUM REACTIONS

Two main theories have been advanced to explain these reactions the theory of Ehrlich and the theory of Bordet The former theory assumes a chemical union between the antigen and the antibody, the other interprets the reactions as adsorption phenomena in which the antibody is adsorbed by the antigen In spite of some opposition the theory of Ehrlich has acquired a dominant position in medical literature, and its general outline is familiar to all who have even the scantiest knowledge of medical sciences

According to the views of the Ehrlich school each of the serum reactions is due to the existence of a separate and particular antibody These various and hypothetical antibodies have been arranged in three classes *Receptors of the first order* To this class belong the antitoxins, which possess a haptophore group, a grouping of atoms capable of satisfying the affinities of the corresponding grouping in the haptophore molecule of the homologous toxin The toxin molecule is thus rendered harmless for it is no longer able to combine with the cells of the body *Receptors of the second order* These have in addition to the haptophore group, a second group, the ergophore group, which by virtue of its chemical constitution is able to bring about the change peculiar to the particular type of antibody To this class belong the precipitins and agglutinins The haptophore group of the agglutinin combines with the bacterium, and subsequently the ergophore group proceeds to produce agglutination *Receptors of the third order* In addition to the haptophore group the antibodies possess a complementophile group, which combines with a substance called complement which is necessary to complete the lysis of a corpuscle or bacterium The antibodies concerned in the complement-fixation reaction are held by many to constitute a separate class of amboceptor and the opsonins or bacteriotropins are also considered to belong to this group

It is assumed, then that each serum reaction is an entirely separate and distinct phenomenon the result of the action of a highly specialised chemical substance expressly manufactured for the purpose A precipitin is a body which combines with homologous antigen, and then by virtue of a special chemical formula proceeds to precipitate it It is entirely distinct from the complement binding amboceptor which is structurally adapted to perform the specific function of complement fixation It is manifest that the side chain theory affords no explanation whatever of the mechanism of the serum reactions It may as a matter of mere terminology, be convenient to say that any serum contains an agglutinin for *B typhosus* but the process of agglutination is in no way explained by saying that the agglutinin possesses two groups the one a haptophore which combines with the bacillus the other an ergophore which produces agglutination We already know that clumping occurs and that the reaction is specific Ignorance, however aptly veiled in an attractive terminology remains ignorance

With each addition to the store of experimental fact new substances have been imagined and endowed with the appropriate functions To difficulties in the interpretation of the reaction between toxin and antitoxin we owe the coining of such words as prototoxoid syntoxoid and epitoxoid The observation that bacteriolysis does not occur in the presence of a great relative excess of antiserum led Neisser and Wechsberg (1901) to elaborate the hypothetical conception of complement deviation[1] (*Komplement Ablenkung*). The experimental facts are explained in this case by supposing that free amboceptors have a greater affinity for complement than those which have effected union with the receptors of the bacillus Ferrata (1907) showed by precipitating the euglobulin of fresh serum that two substances appeared to be necessary for complement action The names mid piece and end piece fraction of the complement were accordingly coined, and the diagrams which accompany Brand's article (1907) are examples of the attempt to make new experimental data conform to the limits of a ruling hypothesis

---

[1] Complement deviation (*Ablenkung*) should not be confused with the more familiar complement fixation (*Bindung*)

A theory, right or wrong, is of value as long as it tends to progress and further investigation, and it is notorious that the researches of Ehrlich and his school have yielded results of high theoretical interest and great practical value, in the realms alike of diagnosis and therapeutics Nevertheless, the outstanding genius of Ehrlich and the greatness of his discoveries have tended to give to the theory associated with his name a position comparable to that of a well known law of physical or biological science New observations have been held to be explained if they were shown to be consistent with the side chain hypothesis But agglutinins, precipitins, amboceptors are mere words, and a passive belief in the existence of such bodies tends to impede rather than advance our understanding of what is actually taking place In our present state of ignorance of the nature of the reaction it seems undesirable to use a terminology which implies a knowledge which we do not possess

We know that when substances containing antigens are mixed with substances containing antibodies a change takes place, and we can obtain indirect evidence of this change by observing certain phenomena such as precipitation, agglutination, or lysis It seems to me probable that these phenomena are the result of one fundamental reaction which takes place between antigen and antibody The so called serum reactions, precipitation, agglutination, lysis, complement fixation, and the opsonic reaction constitute different methods for the indirect observation of one reaction which underlies and is essential to them all[1] They are in fact, accessory phenomena, and their demonstration is dependent on accessory characteristics in the reagents which we employ For all the reactions which can be demonstrated in a test tube it is only necessary to postulate one kind of antibody

PRECIPITATION

This is a reaction which is usually demonstrated by mixing antiserum with an antigen containing fluid According to the side chain hypothesis the antiserum contains an active substance the precipitin which precipitates the antigen, called in this reaction the precipitinogen That any person who had carried out many precipitation reactions should continue to hold this view is not a little surprising In practice relatively large amounts of antiserum are invariably employed, while the antigen containing serum may be employed in quantities of 0 0001 c c, 0 00001 c c., or in exceptional cases still smaller amounts That a fairly abundant and easily visible precipitate could be derived from such a minute quantity of antigen is scarcely conceivable It is to Welsh and Chapman (1908 to 1910) that we owe a most important observation on this subject These workers showed by gravimetric methods that, under the usual experimental conditions, the greater part, if not all of the precipitate was derived from the antiserum Table I, abbreviated from a paper in the Proceedings of the Royal Society (1907) by Welsh and Chapman, illustrates this point

TABLE I

No of experiment	Weight of egg white homologous protein (dried)	Amount of antiserum (fresh)	Weight of precipitum (dried)
1	2 5 mg	19 c.c	18·0 mg
2	2 5 mg	20 c.c	18·0 mg
5 (a)	1·0 mg	18 c.c.	13 0 mg
5 (b)	Superfluid of 5 (a)	16 c.c.	8 5 mg
5 (c)	5 (b)	18 c.c	4 4 mg

In experiment (1) 2 5 mg dried hen egg white interacted once with 19 c c fresh hen egg antiserum and caused the formation of a deposit weighing 18 mg, or more than seven times the weight of the homologous protein concerned In experiment (5) 1 mg of dried hen egg white interacting (a) with 18 c c fresh hen egg antiserum, brought down a deposit of 13 mg The residual protein in the clear superfluid interacting (b) with 16 c c of a second fresh hen egg antiserum gave a further deposit of 8 5 mg The resulting superfluid, again interacting (c) with 18 c c of a third egg antiserum gave a third deposit of 4 4 mg Thus by allowing 1 mg of the homologous protein to interact successively with three antisera (which did not mutually interact) a total deposit of 25·9 mg was obtained

On the other hand, the weight of the precipitate is directly proportional to the amount of antiserum provided that the mixture contains sufficient antigen to precipitate all the precipitable matter in the antiserum This second point is illustrated in Table II taken from Chapman's paper in the Proceedings of the Royal Society (1910)

TABLE II

Weight of dried egg white.	Volume of antiserum	Weight of precipitate	Weight of precipitate from 1 c c antiserum
14 4 mg	2 c c	3·2 mg	1·6 mg
36 0 mg	2 c c	3 5 mg	1 75 mg
144·0 mg	2 c.c.	3 4 mg	1 7 mg
432·0 mg	2 c.c	3 4 mg	1 7 mg

If, however, the mixture contains an insufficient quantity of antigen precipitation is incomplete and a smaller precipitate is obtained The proof given by Welsh and Chapman that under the usual experimental conditions it is the antiserum which is precipitated by the antigen is of far reaching importance It casts an entirely fresh light not merely on the precipitation reaction, but on the other serum reactions as well

Before leaving the subject of precipitation it is necessary to refer to the importance of the relative proportions of antigen and antiserum in the mixture The importance of this factor is shown in Table III (Dean, 1911) —

TABLE III

—	5 c c dilutions of normal horse serum (antigen)	5 c c of a 1 in 5 dilution of rabbit v horse serum (antibody)	5 c c of a 1 in 10 dilution of rabbit v horse serum	5 c c normal saline solution.
1	Undiluted serum	70 c mm	5 c mm	Clear
2	Diluted 1 in 2	140	30	
3	1 in 4	190	65	
4	" 1 in 8	200	80	
5	1 in 16	110	120	
6	1 in 32	61	60	
7	1 in 64	40	25	
8	1 in 128	30	15	
9	1 in 256	20	7 5	
10	1 in 512	10	5	
11	1 in 1024	7 5	Less than 5	—
12	5 c c. normal saline solution	Clear	Clear	

Three sets of dilutions of horse serum were prepared To one set was added an equal quantity of a 1 in 5 dilution of antiserum, to another set was added a 1 in 10 dilution of the antiserum The third set received an equal quantity of normal saline solution and acted as an antigen control The antiserum controls are shown in the tubes numbered 12 All the tubes were incubated for four hours at 37° C, and then placed overnight in the cold room The tubes were then centrifugalised for one hour The tubes ended in a narrow portion, which was calibrated in such a way that the amount of the precipitate could be accurately determined The relative quantities of the precipitate in each tube are indicated by the figures which give the volume of the precipitate in cubic millimetres

With a 1 in 5 dilution of antiserum the largest precipitate was obtained by adding a 1 in 8 dilution of antigen With half the quantity of antiserum (1 in 10) the largest precipitate was obtained by adding a 1 in 16 dilution of antigen The largest precipitate obtained with the 1 in 10 dilution of antiserum was about half the largest amount obtained by the use of twice as much antiserum (1 in 5 dilution) For any quantity of antiserum there exists a quantity of antigen which is capable within a definite period of time of producing the largest precipitate obtainable from such a quantity of antiserum Table III also illustrates very clearly the inhibitory effect of relative excess of antigen This is plainly seen by comparing the figures in the two columns A 1 in 4 antigen dilution, which constituted a marked antigen excess for an equal quantity of 1 in 10 antiserum produced almost the largest precipitate of the series when mixed with a 1 in 5 dilution of antiserum

The relative proportions of antigen and antibody constitute a factor which is present in all the serum reactions This influence of relative proportions suggests an analogy with the precipitate which is formed when an electro-positive is mixed with an electro negative colloid In this case if the proportions are optimal both colloids are completely precipitated If either constituent is present in relative excess precipitation is incomplete Moreschi (1905) concluded as the result of a series of experiments that precipitin and precipitinogen unite in variable proportion to form a series of precipitates. This result is at variance with the conclusions of Welsh and Chapman. The matter is one which merits further investigation.

---

[1] The reaction which takes place between toxin and antitoxin is not accompanied by any change which can be demonstrated in vitro and appears to be of a somewhat different nature to that which takes place in the serum reactions which are here considered

If, then, antigen is mixed with antibody there follows an aggregation of particles with the formation in all probability of an adsorption compound. This aggregation is an essential part of the mechanism of all the serum reactions, not merely of the precipitin reaction but also of agglutination, lysis, complement fixation, and in all probability the opsonic reaction. If sufficient antiserum is used, and if the proportions of antigen and antibody are correctly adjusted, there is formed a bulky and flocculent precipitate. If the mixture contains a relative excess of either antigen or antibody the aggregation process is less complete. Here it may be mentioned that the ordinary method of performing the test in which a few cubic centimetres of the mixture are placed in an ordinary test-tube is not an ideal method of observing a finely divided precipitate. A mixture of antigen and antiserum which looks as clear as water in an ordinary test-tube may appear opalescent or even turbid if viewed through the length of a polarimeter tube.

THE RELATION BETWEEN THE FORMATION OF A PRECIPITATE AND THE FIXATION OF COMPLEMENT

Complement fixation, which since the introduction of the Wassermann reaction has become comparatively familiar, was first observed by Bordet and Gengou in 1901. Interest in the subject was revived by Neisser and Sachs (1905), who elaborated a practical method for the identification of the blood of different kinds of animals. As to the explanation of the phenomenon considerable controversy has taken place. Gay (1905) came to the conclusion that the formation of a precipitate was the essential cause of the disappearance of complement. Neisser and Sachs, on the other hand, found that the amount of the precipitate and the amount of complement fixed stood in no direct proportions. They were able to observe marked fixation of complement in mixtures in which no precipitate could be recognised. They considered that the complement united with the complementophile group of an amboceptor in strict accordance with the theories of Ehrlich. The view was accordingly propounded that precipitation and complement fixation were separate and independent phenomena. Muir and Martin (1906) found that the fixation of complement was, as a rule, closely associated with the formation of a precipitate, but were not convinced that precipitation formed a complete explanation of complement fixation. They cited as an instance a rabbit v guinea pig serum which produced when mixed with its homologous antigen, a faint cloudiness but no definite precipitate. The capacity for fixing complement, however was possessed by this serum to a very high degree. In other experiments they found that if the antigen was greatly diluted no precipitate was formed, but nevertheless the mixture was able to bind complement efficiently.

The case for the separate identity of precipitins and complement-binding antibodies rests on the following evidence. 1. Certain mixtures of antigen and antiserum in which a definite precipitate formed were shown to have little or no power to fix complement. 2. Mixtures containing very small quantities of either antigen or antiserum may appear perfectly clear and yet be shown to be very efficient for complement fixation. 3. Certain antisera give excellent results in complement-fixation experiments but yield very small precipitates. 4. If during the process of immunisation, daily samples of serum are examined complement fixation can as a rule be demonstrated at an earlier stage than precipitation. 5. If either the antiserum or the normal serum (antigen) be heated the capacity for forming a precipitate may be lost, while the capacity for fixing complement may be retained. Bacterial extract kept for a time loses its power of forming a precipitate with homologous antiserum but is still useful for the complement fixation test. But as will be seen from the following experiments these difficulties can be explained without postulating the existence of two different kinds of antibody.

If a series of mixtures are prepared by adding various quantities of antigen to a constant quantity of a good antiserum it is possible to compare the amount and state of division of the precipitate with the amount of complement fixed (Dean 1911).

Column A represents the results of the precipitation experiment. The tubes 1 to 11 in column A contained a bulk of 10 c c, made up of 5 c c of the diluted goat serum (antigen) and 5 c c of a 1 in 10 dilution of rabbit v goat serum (antibody). The lower portion of each of these tubes was narrow and calibrated. The tubes were incubated for 4 hours at 37° C, and the progress of the precipitation was observed and recorded at regular intervals. Immediately after mixing turbidity appeared in tubes 2 and 3. At the expiration of 10 minutes flocculi were apparent in tubes 2 and 3 and tubes 1, 4, and 5 showed uniform turbidity. After half an hour large flocculi which had formed in tubes 2, 3, and 4, had fallen to the bottom of the tubes and left a clear supernatant fluid. Flocculi had formed in tube 1, but had separated less completely. Small particles were visible in tube 5 and just visible in tube 6. In tubes 7 and 8 turbidity was present without visible particles. After one hour the first 6 tubes showed a deposit and a clear supernatant fluid. Tube 7 showed small particles suspended uniformly throughout its contents. In tubes 8, 9, and 10 a progressively diminishing opalescence was seen. After four hours all the tubes were centrifugalised and the actual amount of the deposited precipitate was read. The figures are recorded in column A.

The columns B, C and D record the results obtained in a parallel complement fixation experiment. To obtain a quantitative estimate of the amount of complement fixed 3 doses of guinea pig serum were employed for each of the 11 mixtures of antigen and antibody.

It is evident from a consideration of Table IV that the proportions of antigen and antibody which produce the largest quantity of precipitate are not those which effect the greatest fixation of complement. Similar results were obtained by mixing a variety of antigens with the homologous antisera. When antigen and antibody are mixed in the proportions most favourable to precipitation the aggregation process takes place energetically and large flocculi are rapidly separated. But if the mixture contains a relatively smaller amount of antigen precipitation is slower and less complete. These are the conditions favourable to

Complement Fixation —This experiment shows the amount of complement fixed by mixtures of typhoid extract and antiserum identical with those used in the precipitation experiments The dilutions of extracts antiserum and fresh guinea pig serum (complement) were all used in a bulk of 0 5 c c After one hour's incubation each tube received 0 5 c c of a 1 in 20 suspension of sheep corpuscles and 0 5 c c of a 1 in 300 dilution of hæmolytic serum (rabbit *v* sheep) The results were read after a second period of incubation lasting two hours

complement fixation Under these conditions the individual particles which form the precipitate are extremely small, but present in the aggregate an enormously larger surface area than the flocculi of a coarser precipitate It seems probable that there is a direct relationship between the surface area of the particles of the precipitate and the amount of complement fixed.

By taking any one antigen and any one antiserum and by varying the relative proportions of these two ingredients it is possible to prepare mixtures which demonstrate either precipitation without complement fixation or complement fixation without visible precipitation The amount of complement fixed is conditioned by two factors (1) The amount of precipitate formed and (2) the rate of precipitate formation Complement is fixed during the very earliest stages of the aggregation process which forms the precipitate Indeed, after the process has advanced to a visible turbidity very little complement is taken up The relative proportions of antigen and antibody which favour rapid and complete precipitation are positively unfavourable to complement fixation If a constant amount of antiserum be taken it will be found, as a rule, that the quantity of antigen which will produce the best complement fixation is many times less than the amount necessary to produce the largest precipitate. The reason why the two reactions do not run a parallel course is not that they are caused by two different sets of antibodies, precipitins and amboceptors, but because they represent two phases or two stages of the same reaction, and it may not be possible to demonstrate both stages under the same conditions A flocculent precipitate represents the complete and final stage of a change which can be recognised in its earliest and incomplete stage by means of the complement fixation method On the other hand, if the mixture contains a very small amount of the antigen the aggregation process is extremely slow and may never proceed to the point at which even opalescence is produced Such a condition is, however, very favourable to complement fixation

The conditions which we have considered are those in which a relatively small amount of antigen is allowed to interact with a relatively large amount of antiserum In these cases, although no visible precipitate is formed, the early stages of aggregation afford exactly the physical conditions which favour complement fixation We must now consider the conditions which obtain in mixtures containing very small amounts of antiserum and in complement fixation tests a good antiserum can always be used in a dilution of 1 in 100 often 1 in 500 or even 1 in 1000 If however, a cubic centimetre of a 1 in 500 dilution of antiserum be mixed with an equal quantity of a suitable dilution of the homologous antigen, not even a trace of a precipitate can as a rule be detected, for such a mixture contains far too little of the precipitable protein of the antiserum What is the mechanism of complement fixation under these conditions? In a series of experiments (Dean 1912) it was shown that if, to a mixture of antigen and antiserum which fixes complement but produces little or no precipitate, there be added fresh guinea pig serum, a very definite and flocculent precipitate is produced although a comparatively long time (up to 24 hours) may elapse before precipitation is complete An example of such an experiment is given in Table V

Table VI

In this experiment tubes were used, the lower portions of which were narrow and calibrated in order that the amount of precipitate formed could be measured Only one quantity of antigen was employed (3 c c of a 1 in 20 dilution of typhoid extract) and one quantity of the antiserum (3 c c of a 1 in 20 dilution of antityphoid serum) The amount of precipitate formed by the simple mixture of the antigen and antibody is shown in the second column Tube 8 The actual bulk of the precipitate was 10 c mm

All the tubes were incubated for 6 hours at 37° C The tubes were then placed in a cool room at 8° C After 24 hours the tubes in the first column were centrifugalised and the deposits observed All the control tubes remained absolutely clear

The table shows that the addition of guinea pig serum to this mixture caused a very marked increase in the bulk of the precipitate In the tubes containing the large quantities of guinea pig serum the bulk of the precipitate was twice and three times as great as the precipitate produced in the simple mixture of antigen and antibody It is difficult to escape the conclusion that the larger precipitates were partly derived from the proteids of the guinea pig serum

Similar results were obtained in a large series of experiments in which various antigen antibody systems were employed Normal horse and normal sheep serum were shown to be as effective as guinea pig serum in adding to the bulk of the precipitate Similar results were obtained if in place of the whole guinea pig serum a solution of guinea pig euglobulin was employed These experiments led to the conclusion that the interaction of antigen and antibody may cause the precipitation of the globulin of a normal serum if such is added to the mixture That this precipitation of the globulin of normal guinea pig serum is an essential part of the mechanism of complement fixation can hardly be doubted It will be remembered that if euglobulin is precipitated from fresh guinea pig serum by distilled water or weak acid, the complement is split in two fractions the so-called mid piece and the end piece The mid-piece fraction is carried down with the precipitated euglobulin while the end piece remains in solution (Ferrata, 1907, Brand, 1907, Liefmann, 1909, Sachs and Altmann, 1909) Moreover, in complement fixation experiments the mid piece is bound to a much greater extent than the end piece (Skwirsky, 1910, Henderson Smith 1910, Sachs and Bolkowska 1910, Amako, 1910, and Gengou, 1911) It may, however, well be doubted if any such substance as the mid piece fraction of the complement exists The action of the so-called mid piece may be entirely due to the physical state of the adsorbed particles of euglobulin

It has already been mentioned that these precipitates, which occurred in mixtures of antigen antibody and complement were often not formed until several hours had elapsed. The tubes were consequently often left overnight in the ice chest This practice led to the observation that these precipitates are formed most readily at a low temperature and that if after the precipitate has formed, the tubes are placed in an incubator at 37° C the precipitate dissolves and the mixture becomes once more absolutely clear On replacing the tubes in the ice chest the precipitate re forms The behaviour of this precipitate which forms at 0° C and dissolves at 37° C strengthens the belief that we are dealing with an adsorption process At the lower temperature the adsorption of euglobulin by the minute particles of the precipitate is more complete. When the antigen is a cell or bacterium susceptible to lysis the result of this aggregation of the particles of euglobulin is the concentration of the lytic agent present in the complement (so-called end-piece) at the surface of the cell which is to be dissolved For the subsequent and distinct reaction which causes the solution of the cell envelope a relatively high temperature (37° C) is necessary or at any rate, desirable. If the fixation of complement is dependent on an adsorption process we should expect that the reaction would take place with greater facility at a low rather than a high temperature

(4) 1 in 40	■	■	◲	■	□	◲	■	■
(5) 1 in 80	■	■	■	■	□	■	■	■
(6) 1 in 160	■	■	■	■	◨	■	■	■
(7) 1 in 320	■	■	■	■	■	■	■	■
(8) 0 5 c c saline					■	■		

In the experiment reproduced in Table VII duplicate sets of the bacterial extract, the antiserum and the complement were prepared Set A was warmed to 37° C and Set B was cooled to 0° C Antigen, antibody, and complement were then mixed in the proportions indicated in the table Set A was then kept for half an hour at 37° C and Set B for half an hour at 0° C Both sets were then exposed to room temperature for one hour Blood and hæmolytic serum were then added to each tube and all tubes were then incubated for two hours at 37° C The results show a very marked difference between the two sets

This experiment shows that in a mixture of typhoid extract and antityphoid serum far more complement is fixed at 0° C than at 37° C Similar results have been obtained with serum and homologous antiserum and with the Wassermann reaction

Moreover, if an experiment be devised to show the rate at which the reaction occurs at the two temperatures it is possible to demonstrate that, although the reaction takes place more rapidly at 37° C, the actual amount of complement fixed is much greater at 0° C This result is best explained on the assumption that complement fixation is a process of adsorption

AGGLUTINATION

The explanation of the agglutination reaction as an adsorption phenomenon has been the thesis of many contributions to the literature of immunity Bordet (1899) considered that agglutinin is adsorbed by the bacilli as dye is adsorbed by filter paper The aggregation of the bacilli is then brought about by changes in the molecular attraction between the bacilli and the surrounding medium The question of agglutination was very thoroughly studied from the adsorption standpoint by Craw (1905) Craw showed that the rate of addition of bacillary suspensions to agglutinating serum is a factor determining the amount of agglutinin fixed by the bacilli By adding a suspension of bacteria in parts to the antiserum Craw was able to show that more agglutinin was removed than is the case when the whole amount of bacillary suspension is added at once

The process of agglutination is probably brought about by an interaction between the antiserum and antigen which has passed out from the bacillus into the medium which immediately surrounds it The result of this interaction is the aggregation of the particles of the globulin of the antiserum on the surface of the bacillus In other words, the proteins of the antiserum are adsorbed by the bacillus For the production of agglutination the presence of precipitable protein is essential. If to a mixture of bacillary emulsion and diluted antiserum there be added a third ingredient, normal serum the agglutination of the bacteria is rendered more complete This reinforcement of the proteins of the antiserum by those of a normal serum has been called conglutination This phenomenon was described independently in 1906 by Muir and Browning and by Bordet and Gay

The substance present in normal serum which is able to aid the agglutination of red cells or bacteria by the homologous antiserum appears to be the euglobulin (Dean, 1911) The effect of adding various dilutions of euglobulin solution to mixtures containing sheep cells and various quantities of the homologous antiserum is seen in Table VIII

TABLE VIII

	1 c c of dilution of hæmolytic serum rabbit *v* sheep	+ 1 c c. middle-piece solution diluted					+ 1 c c. normal saline
		1-10	1-20	1-40	1-80	1-160	
1	1-10	++++	++++	++++	++++	++++	++++
2	1-20	++++	++++	++++	++++	++++	++++
3	1-40	++++	++++	++++	++++	++++	++++
4	1-80	++++	++++	++++	+++	+++	++
5	1-160	++++	++++	++++	+++	+	+
6	1-320	++++	++++	++	++	0	0
7	1-640	+++	++	+	0	0	0
8	1-1280	+++	+	0	0	0	0
9	1 c c. normal saline	0	0	0	0	0	0

Each tube contained a volume of 3 c.c made up of 1 c c. of a 1 in 20 suspension of washed red cells of the sheep 1 c c of a dilution of heated hæmolytic serum (rabbit *v* sheep) and 1 c c of the diluted middle piece solution The tubes numbered 9 in each row, contained no immune serum and the bulk was made up to 3 c.c by the addition of 1 c c of normal saline solution In these tubes no agglutination occurred the middle piece solution by itself being unable to agglutinate the red cells The tubes in the last column contained 1 c c of the suspension of red cells, 1 c c of a dilution of the hæmolytic serum, and 1 c c of normal saline solution *The agglutinative power of the immune body acting by itself is shown in this column* In the remaining columns is shown the *effect of the combined action* of the immune body and the middle piece solution

That in such a reaction the euglobulin is actually precipitated may be shown by an experiment *similar to that* shown in Table IX

TABLE IX

Tube	Solution of laked corpuscles	Antiserum rabbit v sheep cells 1 in 200	Normal saline solution	Solution of middle piece 1 in 10	Normal saline solution
	c c	c c	c.c	c c.	c c
1	5	5	—	10	—
2	5	—	5	10	—
3	5	5	—	—	10
4	—	5	5	10	—

One cubic centimetre of thoroughly washed sheep corpuscles was laked with 9 c c *of distilled water* The solution of corpuscles was made up to the usual saline content by the addition of 10 c c of 1 7 per cent sodium chloride solution After filtering many times through filter paper a perfectly clear solution was obtained, representing a 1 in 20 solution of red corpuscles in *normal saline The following* mixtures were then prepared —

In tube 1, 5 c c of the solution of corpuscles was added to 5 c c of the diluted antiserum In the control tubes 2, 3 and 4 the ingredients indicated in the first three columns were mixed *The volume in each tube* was then 10 c c All the tubes were allowed to remain for *one hour at room* temperature They were then examined, and the contents were found to be absolutely clear To tubes 1, 2, and 4 were then added 10 c c of the 1 in 10 middle piece solution, to tube 3 was *added 10 c c of normal saline solution* All four tubes were then incubated for four hours at 37° C and then placed for 12 hours in a cool chamber at about 8° C Tube 1 was then found to contain a small but definite white flocculent deposit The three control tubes remained absolutely clear

CONCLUSIONS

In discussing the merits of rival theories of the mechanism of the *serum reactions it has been frequently observed* that Ehrlich s hypothesis *alone provides an explanation* of the problem of specificity The value of the side chain theory as an explanation of specificity may however, be doubted To say that antigen unites with antibody as a key fits a lock is no explanation at all It is merely a diagrammatic representation of the supposed facts Of the nature of the fundamental reaction between antigen and antibody we have, at the present time, no knowledge But, in all the serum reactions which have been above considered the immediate consequence is an aggregation of globulin particles around the antigen The degree *to which the* aggregation or precipitation proceeds *depends entirely* on the experimental conditions, on the relative proportions of antigen and antibody in the mixture, on the nature of the antigen containing substance, red corpuscle bacillus, or normal serum on the presence of some third factor, a normal serum containing complement or conglutinin In other words the various serum reactions are various methods of observing and measuring one single reaction The simplest of these reactions is the precipitation reaction for *in it* the formation of the precipitate is directly observed In the other reactions the aggregation of particles *may* be less *complete* and the change *is measured* by indirect methods

The main *phenomena* are most readily accounted for by Bordet s adsorption theory, and no useful purpose would seem *to* be served by postulating the existence of a separate kind of antibody for each of these reactions The reactions are no doubt of a very complex nature, as all reactions which occur in a mixture of colloids must be and it is *to be* anticipated that great difficulties must be encountered before any entirely satisfactory explanation is arrived at Similar difficulties have been met with in the past, whenever the attempt has been made to explain physiological phenomena in the light of the laws of chemistry and physics These difficulties will in time be met and with a more perfect knowledge of the mechanism of the serum reactions there will be attained a more perfect knowledge of the laws which govern both natural and acquired immunity

Presidential Address

ON

THE STATE OCTOPUS AND THE MEDICAL PROFESSION

Delivered at the Harveian Society of London on Jan 11th 1917

BY EDMUND CAUTLEY, M D CAMB,
F R C P LOND,

SENIOR PHYSICIAN AT THE METROPOLITAN HOSPITAL AND THE BELGRAVE HOSPITAL FOR CHILDREN

GENTLEMEN,—Year by year the State, like an *octopus* stretching out one or more of its tentacles, grasps and absorbs some portion of the rights privileges, or emoluments of the medical profession or the public I propose to indicate roughly, for time will not permit me to do so in great detail, the methods and progress of this absorption I shall appreciate its value to the public even if it is detrimental to our profession as a whole or to individual sections of it for I hold the opinion that the public welfare is our highest aim and object And I shall try to gauge its *progress* and suggest the best methods for watching and directing its course

CHANGED RELATIONSHIP OF THE STATE THE PUBLIC, AND THE MEDICAL PROFESSION

Half a century ago there was little State interference with the medical profession, and *few burdens,* except registration, were laid upon it At *this remote period* it was *customary* for the eminent lecturer who gave *an opening* address at a medical school to speak in grandiloquent language of the noble aims of our profession It was generally insisted that the student must not enter on its pursuit for the sake of filthy lucre, that the good of the public was alone of importance and that life should be lived on a basis of pure altruism even if it did not provide substantial meals Verily an opening address was a true eye opener The lecturer was usually a successful man who did *not realise the needs of the* common herd or had *forgotten* earlier *impecunious days, though occasionally* one was bold enough to recall the *principle* that the labourer is worthy of his hire or else he spoke with his tongue in his cheek

Even in those days the State exploited the services of the profession, for the medical attendant was compelled to give a death certificate without fee And if he happened to be an officer of a public institution and an inquest were held on a patient who died therein, he had to give expert evidence when called on he had to make a skilled post mortem examination should the coroner *order* one and he had *to* waste valuable *time* in the precincts of the court *and all* this without fee or reward, receiving thanks rarely and ungracious criticism not infrequently No wonder it is

more satisfactory, as this exploitation of our youngest members still exists, that the patient should die on the steps of the hospital rather than across the threshold

Under the Public Health Act of 1875 urban and rural sanitary districts were formed Medical officers of health were appointed in charge of these districts. A diploma in public health was evolved in order to specialise this branch of service and supply evidence of the examinational qualifications of those applying for such posts Since then the medical officer of health though often underpaid, has developed into a being of imposing power and authority under the ægis of the Local Government Board In a sense he is the lily of the profession, for he toils not neither does he spin in the practice of medicine, unless he is in charge of an isolation hospital He is no longer a medical man , he has sloughed his skin and unfortunately has become a departmental official, to whom the interests of the profession are only of minor importance.

Many of the burdens thrust upon our patient shoulders have arisen through the uncontrolled activities of these officers or at their instigation Thus, we have to notify cases of infectious disease Year by year more and more diseases are included in this category , perhaps at first only in some urban district and on the *ipse dixit* of a medical officer of health who speaks to his local council with the dogmatic voice of a god for he alone is assumed to have knowledge of the subject For instance notification of whooping cough is insisted on in some districts in spite of the fact that there is no evidence of its value in reducing the spread of the disease and that, generally speaking, it is not diagnosed among the poorer classes until the whoop is characteristic and the infectious stage almost over Poliomyelitis has also been added to the list, although there is no evidence of its conveyance by direct infection And in 1913-14 ophthalmia neonatorum was wisely added. Of course the main object of notification *is to* control the spread of the disease and isolate its source It sometimes is beneficial in leading to efficient treatment But I *maintain* that no disease should be made notifiable unless such a measure is approved by an authoritative body representative of our profession

In 1907 the medical inspection of school children was authorised by Parliament and medical officers were appointed for this purpose. It was not a great step onward to the treatment of enlarged tonsils and adenoids and errors of refraction. This is partly carried out in hospitals and partly by general practitioners in semi private clinics Seeing that severe hæmorrhage is possible after operation, such clinics ought to be provided with an emergency bed Possibly a further step will be the treatment of all ailments in school children at these clinics and the gradual evolution of numerous small centres of semi hospital practice which *may* or may not be to the advantage of the public and the profession Bear in mind that the school doctor does not treat *these patients* at present He measures and he weighs them collecting masses of statistics He examines them and recommends treatment He, *too*, has become a departmental officer

The Public Health (Tuberculosis) Regulations of 1912 have transferred the treatment *of tuberculous* patients in great measure to public officials with medical qualifications These patients now come under the *conjoint* charge of the medical officer of health, the medical officer of the tuberculosis dispensary and perhaps a sanatorium medical officer It is possible that all cases rich and poor, will eventually be brought under such control and that the treatment of patients with tuberculosis, especially of the lungs, will pass out of the hands of the general practitioners into those of departmental officers

The Mental Deficiency Act of 1913, in operation since April 1st, 1914 has also affected our relations with the public and the State

The National Insurance Act brings home to us the profound changes which are taking place in the relationship between the medical profession and the public, through the medium of the State and its various subordinate bodies, such as county and borough councils municipal bodies, and boards of guardians

"MENTALITIES"

Let me digress for a moment and after the style of a virulent medical controversialist, make a few preliminary remarks on what are at present called "mentalities" Let me premise that ' change" is not synonymous with progress ' though to some minds all change is progress In actual life we meet with two distinct types of mentality, though the bulk of mankind occupy an intermediate position One man goes baldheaded for change He is an iconoclast He destroys an existing institution because he sees evil in it, but he lacks the intelligence or the patience to think out logically the alternative scheme in his mind and the evils likely to develop in his new Utopia. The Insurance Act and other political measures are priceless illustrations of this character

In golden visions a new land legislation was going to hand over that Castle in Spain the latent wealth in our agricultural industry, to those unfortunate men, the failures in the towns They were to go "back to the land" and earn vast sums from the cultivation of the ground in spite of their lack of training and education in one of the most difficult of trades, one which can only be learnt thoroughly by an intimate experience from childhood of all the processes of agriculture

So, too, vast sums were to be drained into the Treasury by means of an increment duty The result, as foretold by the opponents of this measure, has been a great pecuniary loss to the Treasury and a disadvantage to the poor, by reducing the provision of cottages and inducing a rise in rents Rather than attempt to raise money and at the same time put a drag on the building industry, it would have been wiser and cheaper to spend five millions a year, one day s war expenditure, on the building of cottages and other dwellings for the wage-earning classes

Usually the man of this type regards the medical profession as a "monopoly"—that blessed word which damns without explanation of its meaning He little knows that the monopoly consists in the payment of fees to the State, for various degrees and a licence to practise in return for an amount of protection which may be summed up in the power to sue for fees for services rendered Neither the public nor the profession is protected against the evils of quacks and quack medicines Anyone may practise our art in all its branches so long as he does not pretend he is a qualified medical practitioner, though he is liable to prosecution for manslaughter if his patient dies And under the Apothecaries Act of 1815, Section xx , he is liable to a penalty (fine) if he practises as an apothecary Of so little value is this State protection that probably any one of you would make a larger income out of our woolly headed public by dropping your titles and diplomas and advertising a sure remedy for all the ailments of mankind I would suggest a pill which acts mildly and efficiently, purging the vile body of all its ill humours and the affiatus which is not divine

The other type of man is less adventurous in the doing of good or evil by interference with the ordinary routine of life He does not set the world ablaze to advertise his own importance He is devoid of the vanity which lies at the root of the desire to put the world to rights He is more or less satisfied that all is for the best in the best of all possible worlds, and that it is better to endure the ills he knows than to stir up others which may be worse Such a man becomes stereotyped in thought and action in speech more dogmatic as his arteries *harden*, and somewhat intolerant of new ideas even if of German origin Steadily and satisfactorily he conducts the *routine* business of the little world in which he lives Slowly and cautiously he tests and perhaps adopts, new hypotheses and fresh methods of treatment In the face of fresh ideas it is his habit to ' wait and see " Yet, withal, he is tardily progressive, not wildly careering after the exploitation of some new system of treatment or synthetic drug, but patiently sifting and adding to the sum of knowledge

Roughly, the difference between these two characteristic mentalities is like that between youth and age Fortunately most of us occupy an intermediate position, neither wildly iconoclastic nor too rigidly stereotyped Few seem to get beyond middle age in the realms of mind, until the final rapid subsidence into complete senility or retirement into the country and a vegetable existence It is medical men of this intermediate type who are so badly needed on State and municipal committees Were such an influence more in action we should not so frequently be up against some new thing experimental in character rather than of proved value

NEW SCHEMES

I have already pointed out that many a scheme is evolved by the Local Government Board, or a subsidiary council, without obtaining the *consultative* opinion of any representative medical body, and often on the mere *ipse dixit* of

dilution of the hæmolytic serum, and 1 c c of normal saline solution The agglutinative power of the immune body acting by itself is shown in this column In the remaining columns is shown the effect of the combined action of the immune body and the middle piece solution

That in such a reaction the euglobulin is actually precipitated may be shown by an experiment similar to that shown in Table IX

TABLE IX

Tube	Solution of laked corpuscles	Antiserum rabbit v sheep cc is 1 in 200	Normal saline solution	Solution of middle piece 1 in 10	Normal saline solution
	c c	c.c	c.c	c c.	c.c
1	5	5	—	10	—
2	5	—	5	10	—
3	5	5	—	—	10
4	—	5	5	10	—

One cubic centimetre of thoroughly washed sheep corpuscles was laked with 9 c c of distilled water The solution of corpuscles was made up to the usual saline content by the addition of 10 c c of 1 7 per cent sodium chloride solution After filtering many times through filter paper a perfectly clear solution was obtained, representing a 1 in 20 solution of red corpuscles in normal saline The following mixtures were then prepared —

In tube 1, 5 c c of the solution of corpuscles was added to 5 c c of the diluted antiserum In the control tubes 2, 3 and 4 the ingredients indicated in the first three columns were mixed The volume in each tube was then 10 c c All the tubes were allowed to remain for one hour at room temperature They were then examined, and the contents were found to be absolutely clear To tubes 1, 2, and 4 were then added 10 c c of the 1 in 10 middle piece solution to tube 3 was added 10 c c of normal saline solution All four tubes were then incubated for four hours at 37° C and then placed for 12 hours in a cool chamber at about 8° C Tube 1 was then found to contain a small but definite white flocculent deposit The three control tubes remained absolutely clear

CONCLUSIONS

In discussing the merits of rival theories of the mechanism of the serum reactions it has been frequently observed that Ehrlich s hypothesis alone provides an explanation of the problem of specificity The value of *the side-chain theory* as an explanation of specificity may however, be doubted To say that antigen unites with antibody as a key fits a lock is no explanation at all It is merely a diagrammatic representation of the supposed facts Of the nature of the fundamental reaction between antigen and antibody we have at the present time, no knowledge But in all the serum reactions which have been above considered the immediate consequence is an aggregation of globulin particles around the antigen The degree to which the aggregation or precipitation proceeds depends entirely on the experimental conditions on the relative proportions of antigen and antibody in the mixture, *on the nature of the* antigen containing substance *red corpuscle* bacillus or normal serum on the presence of *some* third factor a *normal serum* containing complement or conglutinin In other words the various serum reactions are various methods of observing and measuring one single reaction The simplest of these reactions is the precipitation reaction for in it the formation of the precipitate is directly observed In the other reactions the aggregation of particles may be less complete and the change is measured by indirect methods

The main phenomena are most readily accounted for by Bordet s adsorption theory, and no useful purpose would seem to be served by postulating the existence *of a separate* kind of antibody *for each of these reactions* The reactions are no doubt *of a very complex nature*, as all reactions which occur in a mixture of colloids must be and it is to be anticipated that great difficulties must be encountered before any entirely satisfactory explanation is arrived at Similar difficulties have been met with in the past whenever the attempt has been made to explain physiological phenomena in the light of the laws of chemistry and physics These difficulties will in time be met and with a more perfect knowledge of the mechanism of the serum reactions there will be attained a more perfect *knowledge of* the laws which govern both natural and acquired immunity

more satisfactory, as this exploitation of our youngest members still exists, that the patient should die on the steps of the hospital rather than across the threshold

Under the Public Health Act of 1875 urban and rural sanitary districts were formed Medical officers of health were appointed in charge of these districts. A diploma in public health was evolved in order to specialise this branch of service and supply evidence of the examinational qualifications of those applying for such posts Since then the medical officer of health though often underpaid, has developed into a being of imposing power and authority under the ægis of the Local Government Board In a sense he is the lily of the profession, for he toils not neither does he spin in the practice of medicine, unless he is in charge of an isolation hospital He is no longer a medical man , he has sloughed his skin and unfortunately has become a departmental official, to whom the interests of the profession are only of minor importance

Many of the burdens thrust upon our patient shoulders have arisen through the uncontrolled activities of these officers or at their instigation Thus, we have to notify cases of infectious disease Year by year more and more diseases are included in this category , perhaps at first only in some urban district and on the *ipse dixit* of a medical officer of health, who speaks to his local council with the dogmatic voice of a god for he alone is assumed to have knowledge of the subject. *For instance* notification of whooping cough is insisted on in some districts in spite of the fact that there is no evidence of its value in reducing the spread of the disease, and that, generally speaking, it is not diagnosed among the poorer classes until the whoop is characteristic and the infectious stage almost over Poliomyelitis has also been added to the list, although there is no evidence of its conveyance by direct infection And in 1913–14 ophthalmia neonatorum was wisely added Of course the main object of notification is to control the spread of the disease and isolate its source It sometimes is beneficial in leading to efficient treatment But I maintain that no disease should be made notifiable unless such a measure is approved by an authoritative body representative of our profession

In 1907 the medical inspection of school children was authorised by Parliament and medical officers were appointed for this purpose. It was not a great step onward to the treatment of enlarged tonsils and adenoids and errors of refraction This is partly carried out in hospitals and partly by general practitioners in semi private clinics Seeing that severe hæmorrhage is possible after operation, such clinics ought to be provided with an emergency bed Possibly a further step will be the treatment of all ailments in school children at these clinics and the gradual evolution of numerous small centres of semi hospital practice which may or may not be to the advantage of the public and the profession Bear in mind that the school doctor does not treat these patients at present He measures and he weighs them, collecting masses of statistics He examines them and recommends treatment He, too, has become a departmental officer

The Public Health (Tuberculosis) Regulations of 1912 have transferred the treatment of tuberculous patients in great measure to public officials with medical qualifications These patients now come under the conjoint charge of the medical officer of health, the medical officer of the tuberculosis dispensary, and perhaps a sanatorium medical officer It is possible that all cases, rich and poor, will eventually be brought under such control and that the treatment of patients with tuberculosis, especially of the lungs, will pass out of the hands of the general practitioners into those of departmental officers

The Mental Deficiency Act of 1913 in operation since April 1st, 1914 has also affected our relations with the public and the State

The National Insurance Act brings home to us the profound changes which are taking place in the relationship between the medical profession and the public, through the medium of the State and its various subordinate bodies, such as county and borough councils, municipal bodies and boards of guardians

"MENTALITIES"

Let me digress for a moment and after the style of a virulent medical controversialist, make a few preliminary remarks on what are at present called "mentalities" Let me premise that "change" is not synonymous with 'progress,' though to some minds all change is progress In actual life we meet with two distinct types of mentality, though the bulk of mankind occupy an intermediate position One man goes baldheaded for change He is an iconoclast He destroys an existing institution because he sees evil in it, but he lacks the intelligence or the patience to think out logically the alternative scheme in his mind and the evils likely to develop in his new Utopia The Insurance Act and other political measures are priceless illustrations of this character

In golden visions a new land legislation was going to hand over that Castle in Spain, the latent wealth in our agricultural industry, to those unfortunate men, the failures in the towns They were to go "back to the land" and earn vast sums from the cultivation of the ground in spite of their lack of training and education in one of the most difficult of trades, one which can only be learnt thoroughly by an intimate experience from childhood of all the processes of agriculture

So, too, vast sums were to be drained into the Treasury by means of an increment duty The result, as foretold by the opponents of this measure, has been a great pecuniary loss to the Treasury and a disadvantage to the poor, by reducing the provision of cottages and inducing a rise in rents Rather than attempt to raise money and at the same time put a drag on the building industry, it would have been wiser and cheaper to spend five millions a year, one day's war expenditure, on the building of cottages and other dwellings for the wage earning classes

Usually the man of this type regards the medical profession as a "monopoly"—that blessed word which damns without explanation of its meaning He little knows that the monopoly consists in the *payment of fees to* the State, for various degrees and a licence to practise, in return for an amount of protection which may be summed up in the power to sue for fees for services rendered Neither the public nor the profession is protected against the evils of quacks and quack medicines Anyone may practise our art in all its branches so long as he does not pretend he is a qualified medical practitioner, though he is liable to prosecution for manslaughter if his patient dies And under the Apothecaries Act of 1815, Section xx , he is liable to a penalty (fine) if he practises as an apothecary Of so little value is this State protection that probably any one of you would make a larger income out of our woolly headed public by dropping your titles and diplomas and advertising a sure remedy for all the ailments of mankind I would suggest a pill, which acts mildly and efficiently, purging the vile body of all its ill humours and the afflatus which is not divine

The other type of man is less adventurous in the doing of good or evil by interference with the ordinary routine of life He does not set the world ablaze to advertise his own importance He is devoid of the vanity which lies at the root of the desire to put the world to rights He is more or less satisfied that all is for the best in the best of all possible worlds, and that it is better to endure the ills he knows than to stir up others which may be worse Such a man becomes stereotyped in thought and action in speech more dogmatic as his arteries harden, and somewhat intolerant of new ideas, even if of *German* origin Steadily and satisfactorily he conducts the routine business of the little world in which he lives *Slowly* and cautiously he tests, and perhaps adopts, new *hypotheses* and fresh methods of treatment In the face of fresh ideas it is his habit to 'wait and see" Yet *withal*, he is tardily progressive, not wildly careering after the exploitation of some new system of treatment or synthetic drug, but patiently sifting and adding to the sum of knowledge

Roughly, the difference between these two characteristic mentalities is like that between youth and age Fortunately most of us occupy an intermediate position, neither wildly iconoclastic nor too rigidly stereotyped Few seem to get beyond middle age in the realms of mind, until the final rapid subsidence into complete senility or retirement into the country and a vegetable existence It is medical men of this intermediate type who are so badly needed on State and municipal committees Were such an influence more in action we should not so frequently be up against some new thing, experimental in character rather than of proved value

NEW SCHEMES

I have already pointed out that many a scheme is evolved by the Local Government Board or a subsidiary council, without obtaining the consultative opinion of any representative medical body, and often on the mere *ipse dixit* of

dilution of the hæmolytic serum, and 1 c c of normal saline solution The agglutinative power of the immune body acting by itself is shown in this column In the remaining columns is shown the effect of the combined action of the immune body and the middle piece solution

That in such a reaction the euglobulin is actually precipitated may be shown by an experiment similar to that shown in Table IX

TABLE IX

Tube	Solution of laked corpuscles	Antiserum rabbit v sheep cells 1 in 200	Normal saline solution	Solution of middle piece 1 in 10	Normal saline solution
	c c	c c	c c	c c	c.c
1	5	5	—	10	—
2	5	—	5	10	—
3	5	5	—	—	10
4	—	5	5	10	—

One cubic centimetre of thoroughly washed sheep corpuscles was laked with 9 c c of distilled water The solution of corpuscles was made up to the usual saline content by the addition of 10 c c of 1 7 per cent sodium chloride solution After filtering many times through filter paper a perfectly clear solution was obtained, representing a 1 in 20 solution of red corpuscles in normal saline The following mixtures were then prepared —

In tube 1, 5 c c of the solution of corpuscles was added to 5 c c of the diluted antiserum In the control tubes 2, 3 and 4 the ingredients indicated in the first three columns were mixed The volume in each tube was then 10 c c All the tubes were allowed to remain for one hour at room temperature They were then examined, and the contents were found to be absolutely clear To tubes 1, 2, and 4 were then added 10 c c of the 1 in 10 middle piece solution, to tube 3 was added 10 c c of normal saline solution All four tubes were then incubated for four hours at 37° C and then placed for 12 hours in a cool chamber at about 8° C Tube 1 was then found to contain a small but definite white flocculent deposit The three control tubes remained absolutely clear

CONCLUSIONS

In discussing the merits of rival theories of the mechanism of the serum reactions it has been frequently observed that Ehrlich s hypothesis alone provides an explanation of the problem of specificity The value of the side chain theory as an explanation of specificity may however, be doubted To say that antigen unites with antibody as a key fits a lock is no explanation at all It is merely a diagrammatic representation of the supposed facts Of the nature of the fundamental reaction between antigen and antibody we have at the present time, no knowledge But, in all the serum reactions which have been above considered the immediate consequence is an aggregation of globulin particles around the antigen The degree to which the aggregation or precipitation proceeds depends entirely on the experimental conditions on the relative proportions of antigen and antibody in the mixture, on the nature of the antigen containing substance red corpuscle bacillus or normal serum on the presence of some third factor, a normal serum containing complement or conglutinin In other words the various serum reactions are various methods of observing and measuring one single reaction The simplest of these reactions is the precipitation reaction, for in it the formation of the precipitate is directly observed In the other reactions the aggregation of particles may be less complete and the change is measured by indirect methods

The main phenomena are most readily accounted for by Bordet s adsorption theory and no useful purpose would seem to be served by postulating the existence of a separate kind of antibody for each of these reactions The reactions are no doubt of a very complex nature, as all reactions which occur in a mixture of colloids must be and it is to be anticipated that great difficulties must be encountered before any entirely satisfactory explanation is arrived at Similar difficulties have been met with in the past whenever the attempt has been made to explain physiological phenomena in the light of the laws of chemistry and physics These difficulties will in time be met and with a more perfect knowledge of the mechanism of the serum reactions there will be attained a more perfect knowledge of the laws which govern both natural and acquired immunity

Presidential Address

ON

THE STATE OCTOPUS AND THE MEDICAL PROFESSION

Delivered at the Harveian Society of London on Jan 11th, 1917,

BY EDMUND CAUTLEY, M D CAMB,
F R C P LOND,

SENIOR PHYSICIAN AT THE METROPOLITAN HOSPITAL AND THE BELGRAVE HOSPITAL FOR CHILDREN

GENTLEMEN,—Year by year the State, like an octopus stretching out one or more of its tentacles, grasps and absorbs some portion of the rights, privileges, or emoluments of the medical profession or the public I propose to indicate roughly, for time will not permit me to do so in great detail, the methods and progress of this absorption I shall appreciate its value to the public, even if it is detrimental to our profession as a whole or to individual sections of it for I hold the opinion that the public welfare is our highest aim and object And I shall try to gauge its progress and suggest the best methods for watching and directing its course

CHANGED RELATIONSHIP OF THE STATE, THE PUBLIC, AND THE MEDICAL PROFESSION

Half a century ago there was little State interference with the medical profession, and few burdens except registration, were laid upon it At this remote period it was customary for the eminent lecturer who gave an opening address at a medical school to speak in grandiloquent language of the noble aims of our profession It was generally insisted that the student must not enter on its pursuit for the sake of filthy lucre, that the good of the public was alone of importance, and that life should be lived on a basis of pure altruism, even if it did not provide substantial meals Verily an opening address was a true eye opener The lecturer was usually a successful man who did not realise the needs of the common herd or had forgotten earlier impecunious days, though occasionally one was bold enough to recall the principle that the labourer is worthy of his hire, or else he spoke with his tongue in his cheek

Even in those days the State exploited the services of the profession, for the medical attendant was compelled to give a death certificate without fee And if he happened to be an officer of a public institution and an inquest were held on a patient who died therein, he had to give expert evidence when called on he had to make a skilled post mortem examination should the coroner order one and he had to waste valuable time in the precincts of the court, and all this without fee or reward, receiving thanks rarely and ungracious criticism not infrequently No wonder it is

more satisfactory, as this exploitation of our youngest members still exists, that the patient should die on the steps of the hospital rather than across the threshold

Under the Public Health Act of 1875 urban and rural sanitary districts were formed Medical officers of health were appointed in charge of these districts. A diploma in public health was evolved in order to specialise this branch of service and supply evidence of the examinational qualifications of those applying for such posts Since then the medical officer of health, though often underpaid, has developed into a being of imposing power and authority under the ægis of the Local Government Board In a sense he is the lily of the profession, for he toils not neither does he spin in the practice of medicine, unless he is in charge of an isolation hospital He is no longer a medical man, he has sloughed his skin and unfortunately has become a departmental official, to whom the interests of the profession are only of minor importance

Many of the burdens thrust upon our patient shoulders have arisen through the uncontrolled activities of these officers or at their instigation Thus, we have to notify cases of infectious disease Year by year more and more diseases are included in this category, perhaps at first only in some urban district and on the *ipse dixit* of a medical officer of health, who speaks to his local council with the dogmatic voice of a god for he alone is assumed to have knowledge of the subject For instance notification of whooping cough is insisted on in some districts in spite of the fact that there is no evidence of its value in reducing the spread of the disease, and that, generally speaking, it is not diagnosed among the poorer classes until the whoop is characteristic and the infectious stage almost over Poliomyelitis has also been added to the list, although there is no evidence of its conveyance by direct infection And in 1913-14 ophthalmia neonatorum was wisely added Of course the main object of notification is to control the spread of the disease and isolate its source It sometimes is beneficial in leading to efficient treatment But I maintain that no disease should be made notifiable unless such a measure is approved by an authoritative body representative of our profession

In 1907 the medical inspection of school children was authorised by Parliament and medical officers were appointed for this purpose It was not a great step onward to the treatment of enlarged tonsils and adenoids and errors of refraction This is partly carried out in hospitals and partly by general practitioners in semi private clinics Seeing that severe hæmorrhage is possible after operation such clinics ought to be provided with an emergency bed Possibly a further step will be the treatment of all ailments in school children at these clinics and the gradual evolution of numerous small centres of semi hospital practice which may or may not be to the advantage of the public and the profession Bear in mind that the school doctor *does not* treat these patients at present He measures and he weighs them, collecting masses of statistics He *examines* them and recommends treatment He, too, has become a departmental officer

The Public Health (Tuberculosis) Regulations of 1912 have transferred the treatment of tuberculous patients in great measure to public officials with medical qualifications These patients now come under the conjoint charge of the medical officer of health, the medical officer of the tuberculosis dispensary, and perhaps a sanatorium medical officer It is possible that all cases rich and poor, will eventually be brought under such control and that the treatment of patients with tuberculosis, especially of the lungs, will pass out of the hands of the general practitioners into those of departmental officers

The Mental Deficiency Act of 1913 in operation since April 1st, 1914 has also affected our relations with the public and the State

The National Insurance Act brings home to us the profound changes which are taking place in the relationship between the medical profession and the public, through the medium of the State and its various subordinate bodies, such as county and borough councils, municipal bodies, and boards of guardians

"MENTALITIES"

Let me digress for a moment and after the style of a virulent medical controversialist, make a few preliminary remarks on what are at present called "mentalities." Let me premise that "change" is not synonymous with "progress," though to some minds all change is progress In actual life we meet with two distinct types of mentality, though the bulk of mankind occupy an intermediate position One man goes baldheaded for change He is an iconoclast He destroys an existing institution because he sees evil in it, but he lacks the intelligence or the patience to think out logically the alternative scheme in his mind and the evils likely to develop in his new Utopia The Insurance Act and other political measures are priceless illustrations of this character

In golden visions a new land legislation was going to hand over that Castle in Spain, the latent wealth in our agricultural industry, to those unfortunate men, the failures in the towns They were to go "back to the land" and earn vast sums from the cultivation of the ground in spite of their lack of training and education in one of the most difficult of trades, one which can only be learnt thoroughly by an intimate experience from childhood of all the processes of agriculture

So, too, vast sums were to be drained into the Treasury by means of an increment duty The result, as foretold by the opponents of this measure, has been a great pecuniary loss to the Treasury and a disadvantage to the poor, by reducing the provision of cottages and inducing a rise in rents Rather than attempt to raise money and at the same time put a drag on the building industry, it would have been wiser and cheaper to spend five millions a year, one day's war expenditure, on the building of cottages and other dwellings for the wage earning classes

Usually the man of this type regards the medical profession as a "monopoly"—that blessed word which damns without explanation of its meaning He little knows that the monopoly consists in the payment of fees to the State, for various degrees and a licence to practise, in return for an amount of protection which may be summed up in the power to sue for fees for services rendered Neither the public nor the profession is protected against the evils of quacks and quack medicines Anyone may practise our art in all its branches so long as he does not pretend he is a qualified medical practitioner, though he is liable to prosecution for manslaughter if his patient dies And under the Apothecaries Act of 1815, Section xx, he is liable to a penalty (fine) if he practises as an apothecary Of so little value is this State protection that probably any one of you would make a larger income out of our woolly headed public by dropping your titles and diplomas and advertising a sure remedy for all the ailments of mankind I would suggest a pill which acts mildly and efficiently, purging the vile body of all its ill humours and the afflatus which is not divine

The other type of man is less adventurous in the doing of good or evil by interference with the ordinary routine of life He does not set the world ablaze to advertise his own importance He is devoid of the vanity which lies at the root of the desire to put the world to rights He is more or less satisfied that all is for the best in the best of all possible worlds, and that it is better to endure the ills he knows than to stir up others which may be worse Such a man becomes stereotyped in thought and action in speech more dogmatic as his arteries harden, and somewhat intolerant of new ideas, even if of German origin Steadily and satisfactorily he conducts the routine business of the little world in which he lives Slowly and cautiously he tests, and perhaps adopts, new hypotheses and fresh methods of treatment In the face of fresh ideas it is his habit to "wait and see" Yet, withal, he is tardily progressive, not wildly careering after the exploitation of some new system of treatment or synthetic drug, but patiently sifting and adding to the sum of knowledge

Roughly, the difference between these two characteristic mentalities is like that between youth and age Fortunately most of us occupy an intermediate position, neither wildly iconoclastic nor too rigidly stereotyped Few seem to get beyond middle age in the realms of mind, until the final rapid subsidence into complete senility or retirement into the country and a vegetable existence It is medical men of this intermediate type who are so badly needed on State and municipal committees Were such an influence more in action we should not so frequently be up against some new thing, experimental in character rather than of proved value

more satisfactory, as this exploitation of our youngest members still exists, that the patient should die on the steps of the hospital rather than across the threshold

Under the Public Health Act of 1875 urban and rural sanitary districts were formed Medical officers of health were appointed in charge of these districts. A diploma in public health was evolved in order to specialise this branch of service and supply evidence of the examinational qualifications of those applying for such posts Since then the medical officer of health though often underpaid, has developed into a being of imposing-power and authority under the ægis of the Local Government Board In a sense he is the lily of the profession, for he toils not neither does he spin in the practice of medicine, unless he is in charge of an isolation hospital He is no longer a medical man , he has sloughed his skin and unfortunately has become a departmental official, to whom the interests of the profession are only of minor importance

Many of the burdens thrust upon our patient shoulders have arisen through the uncontrolled activities of these officers or at their instigation Thus, we have to notify cases of infectious disease Year by year more and more diseases are included in this category , perhaps at first only in some urban district and on the *ipse dixit* of a medical officer of health, who speaks to his local council with the dogmatic voice of a god, for he alone is assumed to have knowledge of the subject For instance notification of whooping cough is insisted on in some districts in spite of the fact that there is no evidence of its value in reducing the spread of the disease, and that, generally speaking, it is not diagnosed among the poorer classes until the whoop is characteristic and the infectious stage almost over Poliomyelitis has also been added to the list, although there is no evidence of its conveyance by direct infection And in 1913–14 ophthalmia neonatorum was wisely added Of course the main object of notification is to control the spread of the disease and isolate its source. It sometimes is beneficial in leading to efficient treatment But I maintain that no disease should be made notifiable unless such a measure is approved by an authoritative body representative of our profession

In 1907 the medical inspection of school children was authorised by Parliament and medical officers were appointed for this purpose It was not a great step onward to the treatment of enlarged tonsils and adenoids and errors of refraction This is partly carried out in hospitals and partly by general practitioners in semi private clinics Seeing that severe hæmorrhage is possible after operation, such clinics ought to be provided with an emergency bed Possibly a further step will be the treatment of all ailments in school children at these clinics and the gradual evolution of numerous small centres of semi hospital practice which may or may not be to the advantage of the public and the profession Bear in mind that the school doctor does not treat these patients at present He measures and he weighs them collecting masses of statistics He examines them and recommends treatment He, too, has become a departmental officer

The Public Health (Tuberculosis) Regulations of 1912 have transferred the treatment of tuberculous patients in great measure to public officials with medical qualifications These patients now come under the conjoint charge of the medical officer of health the medical officer of the tuberculosis dispensary, and perhaps a sanatorium medical officer It is possible that all cases rich and poor, will eventually be brought under such control and that the treatment of patients with tuberculosis especially of the lungs, will pass out of the hands of the general practitioners into those of departmental officers

The Mental Deficiency Act of 1913 in operation since April 1st 1914 has also affected our relations with the public and the State

The National Insurance Act brings home to us the profound changes which are taking place in the relationship between the medical profession and the public, through the medium of the State and its various subordinate bodies, such as county and borough councils, municipal bodies, and boards of guardians

"MENTALITIES"

Let me digress for a moment and after the style of a virulent medical controversialist make a few preliminary remarks on what are at present called ‘ mentalities ’ Let me premise that ‘change" is not synonymous with ‘progress" though to some minds all change is progress

In actual life we meet with two distinct types of mentality, though the bulk of mankind occupy an intermediate position One man goes baldheaded for change He is an iconoclast He destroys an existing institution because he sees evil in it, but he lacks the intelligence or the patience to think out logically the alternative scheme in his mind and the evils likely to develop in his new Utopia The Insurance Act and other political measures are priceless illustrations of this character

In golden visions a new land legislation was going to hand over that Castle in Spain, the latent wealth in our agricultural industry, to those unfortunate men the failures in the towns They were to go "back to the land" and earn vast sums from the cultivation of the ground in spite of their lack of training and education in one of the most difficult of trades, one which can only be learnt thoroughly by an intimate experience from childhood of all the processes of agriculture

So, too, vast sums were to be drained into the Treasury by means of an increment duty The result, as foretold by the opponents of this measure, has been a great pecuniary loss to the Treasury and a disadvantage to the poor, by reducing the provision of cottages and inducing a rise in rents Rather than attempt to raise money and at the same time put a drag on the building industry, it would have been wiser and cheaper to spend five millions a year, one day s war expenditure, on the building of cottages and other dwellings for the wage earning classes

Usually the man of this type regards the medical profession as a "monopoly"—that blessed word which damns without explanation of its meaning He little knows that the monopoly consists in the payment of fees to the State, for various degrees and a licence to practise, in return for an amount of protection which may be summed up in the power to sue for fees for services rendered Neither the public nor the profession is protected against the evils of quacks and quack medicines Anyone may practise our art in all its branches so long as he does not pretend he is a qualified medical practitioner, though he is liable to prosecution for manslaughter if his patient dies And under the Apothecaries Act of 1815, Section xx., he is liable to a penalty (fine) if he practises as an apothecary Of so little value is this State protection that probably any one of you would make a larger income out of our woolly headed public by dropping your titles and diplomas and advertising a sure remedy for all the ailments of mankind. I would suggest a pill, which acts mildly and efficiently, purging the vile body of all its ill humours and the afflatus which is not divine

The other type of man is less adventurous in the doing of good or evil by interference with the ordinary routine of life. He does not set the world ablaze to advertise his own importance He is devoid of the vanity which lies at the root of the desire to put the world to rights He is more or less satisfied that all is for the best in the best of all possible worlds and that it is better to endure the ills he knows than to stir up others which may be worse Such a man becomes stereotyped in thought and action in speech more dogmatic as his arteries harden, and somewhat intolerant of new ideas, even if of German origin Steadily and satisfactorily he conducts the routine business of the little world in which he lives Slowly and cautiously he tests, and perhaps adopts, new hypotheses and fresh methods of treatment In the face of fresh ideas it is his habit to ‘wait and see" Yet, withal, he is tardily progressive, not wildly careering after the exploitation of some new system of treatment or synthetic drug, but patiently sifting and adding to the sum of knowledge

Roughly, the difference between these two characteristic mentalities is like that between youth and age Fortunately most of us occupy an intermediate position, neither wildly iconoclastic nor too rigidly stereotyped Few seem to get beyond middle age in the realms of mind, until the final rapid subsidence into complete senility or retirement into the country and a vegetable existence. It is medical men of this intermediate type who are so badly needed on State and municipal committees Were such an influence more in action we should not so frequently be up against some new thing, experimental in character rather than of proved value

NEW SCHEMES.

I have already pointed out that many a scheme is evolved by the Local Government Board or a subsidiary council, without obtaining the consultative opinion of any representative medical body, and often on the mere *ipse dixit* of

some local medical officer of health Sometimes it is initiated by a self appointed leader of the profession, who collects others like unto himself We have had instances of this in the development of the crusade against tuberculosis Occasionally these ' leaders ' are in opposition, as in the painful case of the manifesto published in favour of alcohol But however initiated, the scheme is set in action by an Order in Council or some local by law, and we are expected to carry it out without murmur or protest

As a rule these fresh burdens on the doctor are unaccompanied by fees for the extra work, or at most only nominal ones For instance, the fee for notification of infectious disease used to be 2s 6d for a private and 1s for a hospital case It is not obvious why the extra work should be paid for at a lower rate when it is done by an underpaid doctor attached to a public institution The profession has recently received its just reward for submitting to such an inequality in payment for identical work Its insignificant fee of half a crown has been reduced to a shilling for private cases I wonder that the shilling fee for hospital cases has not been halved And this reduction has been enforced at a time when the doctors are doing an enormous amount of gratuitous work and the cost of living has greatly increased , and it was carried by Members of Parliament receiving £400 a year, of which £100 is free of income tax, at a time when the services of most of them are of little value and their work in the House of Commons has much decreased.

The Insurance Act

The Insurance Act is a great conception inadequately carried out Instead of being used as a vote catching measure and including all employees, no matter their age and health, it should have been started on a smaller scale for the public benefit alone It ought to have been limited at first to employees under 25 years of age, the healthiest class in the community In the course of 40 years all the wage earning classes up to the age of 65 years would have been insured No doubt 40 years is too long for the politician, though but a moment in the life of a nation I believe that the soundest policy would be to start a new scheme on these lines, independent of the present one, which would eventually lapse and be replaced by an efficient Act In its present state the financial basis of the Act is less than doubtfully sound, its administration chaotic, its innumerable regulations almost impossible to understand and the general result one of dissatisfaction Practically it has resulted in a huge club system on a State basis possessing all the evils of the old club system and none of its advantages to the members from a medical point of view, but financially profitable to the doctors and the clerical staff. As far as I can judge, the only advantage to the public is that every insured patient is entitled to demand treatment for the most trivial ailment and a certificate enabling him to obtain sick benefit if unable to work with the result that trivial ailments have become much more frequent and a desire of obtaining a paid holiday has led to their exaggeration

From the public point of view I regard the medical section of the Act as a failure It is not as good as the old club system with its admitted evils Thousands of the insured are dissatisfied and avoid their panel doctors Adequate treatment has not been secured—merely ordinary out patient treatment, the patient being referred to a hospital for more serious ailments

The Government has not carried out Mr Lloyd George's promises Absolute freedom as to choice of doctor is not in force, he must be on the panel Still less is it possible to make a change when desired Permission to make own arrangements' outside the panel have been generally refused

Panel doctors are practically State officials and their sympathy with the patients has diminished There is more illness more malingering and neurasthenia, greater prolongation of illness and an increasing demand for certificates Often a patient obtains a larger income when ill than when at work Disease has to be treated more or less according to rules and the cheaper drugs used for panel patients help to prolong illness

Some complaints from panel patients are trivial and contemptible The members of a society for agricultural labourers complain bitterly that the doctor now charges 5s for examination of an applicant for membership whereas in the old club the fee was only 2s They refuse to pay it and the society is languishing for want of new members It does not appear to have been pointed out to them that the weekly wage of the labourer has gone up more than 5s , that the doctor has also to face the increased cost of living, and that in the old club the doctor took a much more sympathetic interest, regarding it as partly a charity, whereas insurance is a State affair

And I want to lay it down as an axiom, to be borne in mind by every member of our profession, that gratuitous expert services should not be rendered to the State or any rate levying body No such service is appreciated at its true value It is not charitable service to the poor, and merely lightens to an infinitesimal extent the burden on tax and rate-payers many of whom are much better off than the exploited doctor

Payments under the Act

Under ordinary systems of insurance it is customary to pay a premium in advance to cover a definite liability generally for a year The Insurance Act tempers the wind to the shorn lamb, for the insured patient has to pay weekly premiums for six months before becoming entitled to benefit By this means a big fund was formed of contributions from the employers employees, and the State It should have amounted to 13s per female and 15s 2d per male, apart from the State contribution At the end of six months the work of the doctor began, and there does not seem any just reason why he should not have been paid 7s per head at once for each patient accepted by him Apparently the accumulated preliminary fund was devoted to payment for clerical work a great burden on the finance of the Act—a veritable old man of the sea

The Act fixed an annual capitation grant for medical treatment and Mr Lloyd George frequently stated it would be at least 7s , possibly more, as there was a lien on a floating sixpence But agreements between the State and the profession are apparently only to be kept by the latter In step the Insurance Commissioners with powers above and not under the control of Parliament, and, subsequent to the signature of these agreements, regulations are issued which make the annual capitation fee a sum of no definite amount and not payable within certain limits of time The panel doctor receives an unnamed sum paid on uncertain dates and "as soon as may be" after its receipt by the Commissioners

The medical profession undertook the treatment of the insured for a minimum fee of 7s per annum For 1915 the payment was 5/7 96 per head This is explained by the Commissioners as an equivalent payment because some of the doctors' lists are inflated It is a method for counteracting the errors due to inefficient book keeping It creates great injustice A doctor with an uninflated list receives a grant deficient to the extent of 20 per cent The Commissioners have also determined that their liability to the panel doctor ceases with the death of the patient, although the doctor undertook the contract for a year If the insured person dies on the first day of the year the medical fund is only to get 1/365th part of 7s , and this in spite of the fact that the Commissioners have received payment for six months in advance It does not appear that the State is carrying out its bargain fairly

New Regulations for 1917

Clause 3 deals with the provision of medical services by any public authority over and above those provided by panel doctors It states with dangerous vagueness that under such circumstances the practitioner ' shall take such other steps as may be reasonably necessary in order that the patient may derive full advantage from the provision of such services " Obviously the Commissioners will decide what is 'reasonable ' and, as far as one can judge they expect the doctor to provide particulars as to the past history diagnosis and treatment , take and send specimens for laboratory examination , and attend if necessary with the patient for consultation No extra payment is suggested for this fresh burden which may become excessive And there is no safeguard against the extension of so-called reasonable provisions This regulation gives the Commissioners power to increase the duties of the panel doctors without compensation It has been accepted at present for the treatment of venereal diseases which are said to have increased very greatly and require more adequate methods of control But it may be applied in many ways if consultative advice is to be placed within the reach of panel patients, giving the doctor much extra work and with no extra expense to the patient Instead of reducing the annual capitation grant the tendency will be to increase the doctor's duties and obligations

The Disabled Soldier and Sailor

The disabled soldier and sailor have created another problem for the doctors and Commissioners Weak minded sentimentalists nobly say that the medical profession should shoulder the burden of looking after these heroes But it is the State which should bear the burden, not an individual section of the community Had the Government with a little foresight and apparent generosity paid into the insurance funds the full amounts due from them as employers, the full contributions of their employees and the State grant, they might have been justified in saying that, as the medical profession had received the insurance premiums for medical services during the war, they must undertake the subsequent liability But an extra burden has fallen on the panel doctors during the war, for a huge number of healthy lives have been removed from insurance, and the relative proportion of illness among the remainder is naturally greater It would be grossly unfair for these men to come back into insurance with an increased sickness liability and the burden of their treatment be thrown on the panel doctors without extra payment. Special financial arrangements should be made for the treatment of the disabled when they are discharged

VENEREAL DISEASES

The provision of treatment for these affections under the public authorities is a great step to more efficient control, limitation of their extension, and efficacious treatment But it is another inroad into the old relationship between the public and the profession if it is made obligatory So far it is not compulsory and the supporters of the scheme have not ventured to "go the whole hog" If so, notification would be essential. The main argument against it is that it would lead to concealment of disease, to evasion of treatment or to treatment by quacks Surely the answer is the abolition of quacks and quack medicines and the punishment by imprisonment of anyone, except a qualified practitioner who undertakes the treatment

Compulsory notification has been adopted for many infectious diseases, as well as for others in which the transmission of infection by personal contact has not yet been adequately proved Why, then, shirk it in this case? Is it because the Government fear the loss of revenue from stamp duties on patent medicines, or the attacks of newspapers which receive large sums of money for advertisements and puffs of these wares? More probably it lies in the absence of social stigma in the present notifiable diseases On the other hand, the moral effect of notification on the rising generation would be enormous Few young men dread infection as much as they fear being "found out" by their parents And the risk of evasion is minimised by the provision of free treatment, for, under the new scheme, it is available for rich and poor and under safeguards as to privacy But the whole scheme is defective firstly, because no really authoritative medical body expressed its opinion thereon, secondly, because it establishes a new class of specialist, and thirdly, because the safeguards as to privacy are likely to prove illusory

THE OUTLOOK

The united efforts of panel practice, of State and municipal treatment of tuberculosis venereal and infectious diseases, the possible provision of ante natal and post-natal clinics and the existence of numerous departmental medical hybrids in the shape of medical officers of health school doctors Poor law and asylum doctors tend to the establishment of a State medical service An additional influence will be the return from the war of a large number of medical men, with no experience of civil practice, who may lack the means or the inclination to enter on such a mode of livelihood and who may have become enamoured of an annual stipend, fixed duties liberal freedom and the independence of character acquired in the treatment of those submitted to their tender care and unable to change their doctor Many will be disposed to sink to the level of the salaried official Meetings have already been held in France at the instigation of certain politicians, for the discussion of such a public service.

It is probable that in time each panel doctor will be limited to a definite number of panel patients—say, two to three thousand From this it will be only a small step and perhaps it may be advocated by the doctor, that panel practice should be limited in area and that each such doctor shall have charge of all the insured patients in a limited district Of course, this would abolish the promised free choice of doctor, but I fancy this privilege is not often obtained or of much value The natural sequence will be the conversion of panel practice into one of whole time appointments And the insurance of dependents will make this more certain, as finance on present lines will be impossible It is obvious also that if clinics and pathological laboratories are provided for venereal diseases a similar demand will be made for panel patients with other ailments And, indeed, it seems logical that, if the insurance scheme is to be worked adequately on its medical side, it must be extended to the provision of hospital treatment with all the advantages pertaining thereto Our hospitals will have to be assisted by the State or out of the rates or taken over by the State I am strongly opposed to the idea of a State medical service, but I see no great objection to hospitals receiving such assistance It may necessitate a certain amount of supervision or control, possibly through the occasional visit of an inspector or by a representative on the committee of management The amount of assistance would have to be proportionate to the work done and the facilities provided There is no justification for hospitals putting their resources provided as a charity by voluntary subscribers, gratuitously at the disposal of a State or rate paid medical service

Naturally there would be a big increase in hospital expenditure The visiting staff of London hospitals receives no payment or merely a nominal one and is perfectly satisfied to give its expert aid and much time in a charitable cause. But, although it is often assumed that we will continue to give gratuitous services in return for a few gracious words of praise and an occasional title of honour, more often than not granted to some one or other of the less deserving of the profession I think it will soon be realised that it is not charity to give such services to the State.

Recently there has been a striking illustration of the manner in which the medical profession is exploited Although the State is responsible for the health of its officers as well as the rank and file and reserves to its representatives the decision as to the capacity and fitness of the individual, it has accepted through the Red Cross Society and rich civilians the gratuitous services of a large number of our profession for the treatment of these officers And I desire to remark that the treatment of officers on these lines in private houses, more or less suitable, is not, and cannot be, as good as that of the rank and file in the numerous large and well appointed hospitals at their disposal, with the best conveniences for examination and treatment The lack of a resident medical officer, a pathological apparatus and X ray apparatus, not to mention other defects, is a grave drawback It is marvellous that there has been no outcry against a system so unfair to our officers

I think it will be admitted that when valuable aids to the diagnosis and treatment of illness of all descriptions are at the disposal of the present panel patients they will be extended for the benefit of their dependents All those receiving a weekly wage and (or) below the income tax limit, will be included Do you think that the lower middle class will be content to see the bulk of the nation provided with the best possible medical treatment for which *they* are mulcted in high rates and taxes without demanding similar provision on a better scale as to environment, at a higher annual insurance fee? Treatment in a private ward in a properly equipped hospital is obviously much superior to that of any nursing home or private house Hospitals will have to be enlarged to provide special wards for this class —The nation will be divided into the insured and the non insured Possibly the large group of the insured will be treated by State official doctors and the remainder will still exert the right of free choice of doctor and payment for services rendered The State official will be a superior type of Poor law doctor

A State medical service will *not* be economical though perhaps less extravagant than the panel system It is suitable for those under discipline, but we do not want the nation under the heel of medical drill sergeants No doubt there has been immense improvement in the control and prevention of disease by the *medical department of the* Local Government Board And a certain amount of valuable work has been carried out in laboratories in reference to the cause of particular diseases School medical officers have done good work in securing efficient treatment for hundreds of children who *would otherwise* have been neglected But, so far, I have not noticed much evidence of any advance in scientific medicine, though the extension of treatment has been great and beneficial Nor have I observed much original work done by the present State medical service—namely the Poor law doctors

Further encroachment on private practice will ensue from the extension of sanatorium benefit to dependents Wild cat schemes have been mooted Recently it has been suggested that as sanatorium treatment has not produced any marked effect on the prevalence of tuberculosis, it would be better to insist on the wholesale migration of the tuberculous from unhealthy surroundings to properly supervised dwellings in pure air It certainly would be a wholesale migration And yet many develop tuberculosis under such conditions while others sometimes recover though living in a most unfavourable environment

SUGGESTIONS

I hope I have made it clear that our relations with the State and the public are in a state of flux and that it is dependent on individual members of the profession to watch and direct the course of the current Unfortunately we have no representative body which possesses the complete confidence of our profession or the power to enforce its resolutions The British Medical Association diminished its rapidly increasing influence by allowing some members of its council to make use of it for political purposes in connexion with the Insurance Act. At first it was remarkably successful in organising *the profession in opposition to the Bill* on certain lines, but some of its members broke up the concordance by holding meetings in support of the Bill *Incidentally I may remark they remained members of the* Association

Still it is possible for the British Medical Association if managed with greater tact, more tolerantly, and for the benefit of the profession as a whole, rather than for the advancement or advertisement of sections or individuals to obtain and retain a valuable advisory and directing hand in the future *As our only active representative body it should* receive our support, even if we do not invariably agree with its policy in particular cases

I am strongly of the opinion that it is of the utmost importance for medical men to take a greater part in local politics and act as representatives on county councils and other local bodies The selection of candidates for such posts should be made by the various branches of the British Medical Association or at a joint meeting of members and non members But it must be borne in mind that such candidates must have no political axe to grind and that the welfare of the public and the profession is their sole object We do not want a repetition of the scandals in connexion with the appointments at the time the Insurance Act was in the throes of labour Nor do we want representatives who have *retired from* practice through age incompetence or infirmity, for such posts are not those of *otium cum dignitate* Granting efficacious leadership *it will be possible to* develop a medical service suitable to the genius of the nation out of the present state of chaos which I have somewhat inadequately *pictured Above all under proper leadership* it will be possible to put forward practical schemes carefully thought out under medical guidance rather than have to carry out the imperfectly devised experiments to which we and the public are subjected

---

THE LATE W A LAUDER SMITH M A M B B C CANTAB —Dr Lauder Smith died recently at his residence Wells Somerset from pneumonia following influenza in his fifty second year The deceased was highly esteemed in Wells where he had several public appointments The chairman of the Wells board of guardians in alluding to the loss the board had sustained by the death of their district medical officer said Dr Smith had lived a beautiful life of self sacrifice and had literally worn himself out for others

CASES OF CEREBRO-SPINAL FEVER IN THE ROYAL NAVY—AUGUST 1ST, 1915, TO JULY 31ST, 1916

BY H D ROLLESTON, C B, M D CANTAB, F R C P LOND

TEMPORARY SURGEON GENERAL, R.N CONSULTANT PHYSICIAN TO THE ROYAL NAVY ROYAL NAVAL HOSPITAL, HASLAR
SENIOR PHYSICIAN ST GEORGE'S HOSPITAL

(1) *Incidence of the Cases*

DURING the year August 1st 1915 to July 31st, 1916 there were 104 cases of cerebro spinal fever in the Royal Navy, as compared with 170 cases during the first year of the war This fall in the number of cases must be correlated with the contemporaneous fall in the incidence of the disease both in the civil population and also in the Army in this country [1] Although the fall in the general incidence of the disease is probably the main factor in the smaller incidence in the Navy it should be borne in mind that great care has been taken in prophylaxis, and that in the first half of 1916 bacteriological examination of swabs from the throats of new entries was made at Haslar, Chatham, Plymouth, and at Greenwich of non contacts (new entries and drafts for sea) in order to detect "carriers" Out of *10,852* ratings examined *298* or 2 7 per cent, carriers were thus detected and isolated Not only has the incidence been smaller, but it has been less widespread for no case occurred at Blandford Camp or in the Akbar Establishment, in both of which there were a few cases during the first year of the war At the Deal depot which was responsible for 25 cases *during the first year of the war, there were 2 cases only in* the second year No case has occurred during the war at either Osborne or Dartmouth Royal Naval Colleges

The cases occurred in the Plymouth district (28) Portsmouth district (27) Chatham district (18), at Shotley (11) at the Crystal Palace depôt (8), at Deal (2) and 10 cases on sea going ships During the first two years of the war out of 274 cases of cerebro spinal fever in the Navy there were 22, or 8 per cent, with 13 deaths in sea going ships In one ship only was there more than one case (2)

The monthly incidence with the results is shown below As in the first year of the war, the largest number of cases and of deaths occurred in February

		Cases	Deaths		Recoveries
1915	August	4	2 or	50·0 p c	2
	September	4	3	75·0	1
	October	3	1	33 3	2
	November	6	5	83 0	1
	December	8	4	50·0	4
1916	January	8	3	37 5	5
	February	26	7	26 9	19
	March	20	6	30·0	14
	April	7	2	28 5	5
	May	7	0	—	7
	June	3	2	66 7	1
	July	8	2	25·0	6
		104	37		67

Age incidence —Among the 104 cases in the Navy 70, or 67 3 per cent, were under 20 years of age (83 or 79 8 per cent, being under the age of 25 years) and the number of cases progressively diminished in the succeeding decades The percentage of deaths was lower under 20 years than in any of the succeeding decades The average age of the 104 cases was 20 4 years of the fatal cases 22 2 and of the recoveries 19 4 years The extremes of age were 15 and 46 years

Age periods	Number of cases and percentage of the total 104 cases		Deaths and percentage in the age periods	
15 to 19	70 or	67 3 p c	20 or	28 5 p c
20 29	24	23 1	12	50·0
30 39	6	5 8	2	33 3
40 49	4	3 8	3	75 0
	104		37	

* The case which recovered was invalided and died suddenly six months later the coroner's inquest finding pneumonia as the cause of death

---

[1] For this information I am indebted to Surgeon [illegible] [illegible] H A C

In the first year of the war 60 6 per cent of the cases were under 20 years of age

Mortality —Out of the 104 cases 37, or 35 6 per cent, proved fatal; this contrasts favourably with the mortality of 90, or 52 9 per cent, among the 170 cases during the first year of the war

Ranks and ratings —There were two officers—a midshipman Royal Naval Reserve (aged 18) and a surgeon probationer (aged 21) who both recovered The 102 ratings were as follows Boys (seamen class) 39 (7 deaths), seamen 22 (11 deaths), stokers 13 (6 deaths), marines 11 (3 deaths) engine room artificers 5 (2 deaths), officers' stewards 3 (all fatal, average age 20 years), carpenter's crew 2 (1 death), boy servants 2 (1 death), cook's mate 1 (recovery), plumber's mate 1 (recovery), armourer's crew wireman 1 (fatal), trimmer 1 (recovery), boy artificer 1 (fatal)

(2) *Remarks on Some Clinical Aspects*

Onset —The mode of onset sometimes varied from the common form characterised by fever malaise, headache and vomiting Eight patients when first discovered were in an unconscious condition, and 3 of these had fallen out of their hammocks, one of these, with a graze on the forehead, blood about the nostrils, and vomiting was regarded for some days as a case of fractured base Of the 8 cases with this apoplectiform onset, 4 proved fatal In 4 cases in February respiratory symptoms were so well marked as to suggest pneumonia or acute bronchitis In 1 case the prominence of abdominal symptoms gave rise to an initial diagnosis of appendicitis

In 11 cases at least the disease began very shortly (within three days) after going on leave (6 cases) or returning from leave (5 cases) and in some instances considerable fatigue must have been entailed by the length of the journeys In one instance the disease appeared three days after arriving on leave at Gosport from the Grand Fleet In the 5 cases in which the disease appeared shortly after returning from leave the question of infection when on leave arises In 13 cases the disease occurred within three weeks of joining the Service and exposure to the trials incident to this change of life In 3 cases the disease followed the onset of measles after an interval of about ten days As these cases were already under observation in hospital it is improbable that the initial mottled rash of cerebro-spinal fever was regarded as measles In two other cases the disease attacked patients already in hospital for a lacerated finger and pleurisy respectively In 5 cases (4 fatal) meningitis, in which the cerebro-spinal fluid was proved bacteriologically to contain meningococci supervened on otitis In isolated instances drunkenness and head injury (1 case), influenza and vaccination (4 cases) immediately preceded the onset In 1 case pneumonia and cerebro-spinal fever co-existed These various factors may have so reduced the bodily resistance as to enable saprophytic meningococci in the naso pharynx to invade the system

Rashes were recorded in 51 or 49 per cent, out of the 104 cases, in 41 cases the rash was petechial or hæmorrhagic and 15 or 36 6 per cent, of these proved fatal a mortality percentage very little higher than that (35·6) of all the 104 cases In 1 case with a petechial eruption hæmorrhagic bullæ appeared on the ankles four days after the rash In 5 cases there was a macular rash with 1 death and in 5 cases a rose rash with 1 death The mortality of the 51 cases with rashes was therefore 17, or 33 3 per cent.—namely slightly lower than the mortality of the total 104 cases In the first year of the war, rashes occurred in 102, or 62 6 per cent, of 163 cases and the mortality of the cases with rashes was 52 (51 per cent) or a little lower than that (52 9) of the total 170 cases Although a very profuse hæmorrhagic rash is extremely ominous the occurrence of a rash is not necessarily of grave significance The rash was nearly always noticed on the first or second day of the disease

Herpes was noted in 21 or 20 2 per cent. of the 104 cases, in 20 cases the herpes was on the lips, in the remaining case it was in the distribution of the nasal branch of the ophthalmic division of the fifth nerve but the cornea was not affected. In one of the cases with labial herpes there was also cervical herpes. In 14 cases there was also an initial rash, in 2 cases the rash and the labial herpes both occurred on the second day of the disease, in the remaining cases the herpes appeared later than the rash, on an average on the fourth day of the disease, the extremes being the second and the eighth days In some instances the labial herpes was very profuse Of the 21 cases 4, or 19 per cent, proved fatal, this mortality is rather more than half that (35 6 per cent) of the total 104 cases, and thus agrees with the ancient belief that herpes in cerebro spinal fever, as in pneumonia, is a good prognostic In the previous year herpes labialis was noted in 35, or 21 5 per cent, of 163 cases—almost exactly the same proportion as in the present series

Rarer manifestations and complications —Ocular symptoms Photophobia, which has been stated to be rare,[2] was noted in 10 cases, conjunctivitis in 5, conjunctival hæmorrhage in 2 panophthalmitis with loss of an eye in 2, strabismus in 8 (5 fatal), ptosis in 3 (2 fatal), nystagmus on the second day in 1 (fatal), and von Gräfe's sign in 1 Hemiplegia occurred in 1 case and weakness of the arm in another case both of these were fatal, facial paralysis in 1 (fatal), dysarthria in 1 (recovery), and dysphagia in 1 (recovery) Delirium tremens occurred in 2 cases (1 fatal) Pericarditis was noted in 2 cases, both of which recovered Recent endocarditis was found after death in 1 case (*vide infra*) and transient systolic murmurs were heard in 4 cases which recovered Status lymphaticus was found after death in 1 case. Hæmaturia due to hæmorrhagic cystitis and pyelitis was seen in 1 case, and 1 patient had polyuria for a few days passing 8 6 and 4 pints of urine daily, while the temperature was about 103° F Epididymitis without any evidence of gonorrhœa occurred once

Synovitis was noted in 4 cases (2 fatal) on the second, fifth, fifth, and sixth days of the disease, in 2 cases the knee was affected, in 1 the ankles and wrists and in 1 the interphalangeal joint of a finger All the cases had a petechial or hæmorrhagic eruption, this fits in with the view that when purpura and synovitis are associated, the latter is due to hæmorrhages into the synovial membrane In the case with arthritis of the wrists and ankles on the fifth day of the disease, pericarditis with synovitis of the wrists ankles, and knees developed on the ninth day, in spite of delirium tremens recovery followed In the first year of the war there were 8 cases (2 fatal) of arthritis Acute otitis supervened in 2 cases both of which recovered

Relapses during treatment are said not to be uncommon and generally to occur in cases of chronic hydrocephalus which terminate fatally There was one case proved to be of this nature in a man, aged 19, the relapse which started after nine days of convalescence being ushered in by a rigor In one case a true relapse or brief second attack occurred seven weeks after the temperature had been normal, and was followed by recovery (*vide infra*)

Mixed infections of the cerebro-spinal fluid were reported in 3 cases, pneumococci in 1 case without any obvious focus, and streptococci in 2 cases (one an otitic case, in the other infection occurred through the lumbar puncture)

Diagnosis —Only those cases in which meningococci were found in the cerebro-spinal fluid have been accepted as cerebro-spinal fever This criterion has very probably led to the rejection of some genuine cases of cerebro spinal fever But no clinical manifestation is pathognomonic of the disease Thus a hæmorrhagic rash, though highly suggestive was present in cases proved bacteriologically to be due to other infections, such as pneumococci, or to be free from micro-organisms The latter group of cases, though unsatisfactory, must be recognised.[3]

A fulminating case of meningitis with a profuse hæmorrhagic rash occurred on Nov 7th, 1915, in a cadet at Dartmouth Bacteriological examination of the cerebro-spinal fluid, which was almost clear and contained a few red blood cells and occasional polymorphonuclear leucocytes, by Fleet-Surgeon H C Whiteside, R.N, failed to show any micro-organisms, the cultures were sterile, and no carriers were detected among 30 contacts There was no necropsy A brother died in infancy from meningitis believed to be tuberculous

Cases with meningeal symptoms, which showed meningococci in the naso-pharynx but not in the cerebro-spinal fluid have been ruled out, as they may have been meningococcic carriers with meningism due to some other cause In this connexion it may be pointed out that during the acute stage of cerebro spinal fever swabs from the naso pharynx are often negative Out of 33 cases of bacteriologically proved cerebro spinal fever meningococci were found in the naso pharynx in 7 or 21 3 per cent only This corresponds with von Lingelsheim s figures of 635 cases of cerebro-spinal fever with 146, or 22 per cent positive cultivations from the naso pharynx [4]

---

[2] Foster and Gaskell Cerebro-spinal Fever p 37 1916 Cambridge

[3] Among 121 cerebro-spinal fluids from cases of meningitis in the French Army Sacquépée Burnet and Weissenbach (Bull Acad de Méd., Par 1915, lxxiv 103–105) found 6 with the features of Widal's puriform aseptic meningitis" in which no micro-organisms could be found by direct examination or cultivation.

Cerebral symptoms (meningism) accompanying acute infections, such as influenza pneumonia, enteric, otitis malaria, may closely imitate cerebro spinal fever, and a certain diagnosis can be made only by lumbar puncture and examination of the cerebro spinal fluid Even if a patient has signs of pneumonia it is possible, as shown by isolated cases in both the recent epidemics in the Navy, that there is meningococcic meningitis as well

From other forms of meningitis lumbar puncture and examination of the cerebro spinal fluid constitute again the most reliable method of diagnosis Even with pre existing otitis it does not necessarily follow that meningococcic meningitis can be excluded, for as mentioned above in 5 cases (4 fatal) meningitis, in which the cerebro spinal fluid was proved bacteriologically to contain meningococci, supervened on otitis

Difficulty might arise in the diagnosis from the meningitic form of acute poliomyelitis in which all the symptoms of meningitis may be present, but "on lumbar puncture the cerebro-spinal fluid escapes under pressure, is clear and on cytological examination may be found to contain an increased number of lymphocytes with a normal or sometimes a diminished sugar reaction and an increased amount of albumin" (Batten [5]) An outbreak in Devonshire and Cornwall in 1911 of what was at first thought to be cerebro spinal fever was shown by R J Reece [6] to be one of acute poliomyelitis and not one of acute poliomyelitis occurring concurrently with cerebro spinal fever In July 1916 there was at Shotley an outbreak of 15 cases with the clinical symptoms of cerebro spinal fever [7] but 4 only were proved to be of this nature Among the remaining 11 cases there was one only which could possibly be regarded as an example of the meningitic form of acute poliomyelitis

In acute osteomyelitis of the spine lumbar puncture may give exit to pus from the extradural space This occurred in 2 cases in the Royal Navy which will subsequently be published In neither of these were there definite symptoms of cerebro-spinal fever but Grisel [8] in a review of this form of osteomyelitis states that although in some cases the symptoms of compression are quite definite and disappear when the abscess is evacuated there are others in which the association with meningitic symptoms and septicæmia renders the diagnosis very difficult

The sequence of events in the two following cases is perhaps, worthy of brief mention

Two brothers from the Fair Isle Shetland had measles in September, 1915 in Haslar One developed cerebro spinal fever 13 days after the onset of measles and died The other who had never been well since the attack of measles died in Haslar three months later from tuberculous meningitis In both cases a post mortem examination was made

(3) *Summary of the Results of Treatment*

Two out of the 104 cases were discovered after death only and therefore were not treated for the disease, 1 case (fatal) received soamin only, and 6 cases of which 4 or 66 7 per cent proved fatal had lumbar puncture only Therefore, out of 9 cases which did not receive serum 7 or 77 8 per cent proved fatal

Among the 95 cases treated by some form of serum the mortality was 30 or 31 6 per cent This result which is in striking contrast to the results of serum treatment in the first year of the war—105 cases with a mortality of 64 or 61 per cent—fully justifies the serum treatment of the disease and is compatible with the widely expressed view that the serums employed in this country during the first year of the war were largely deficient in antibodies Flexner s serum, made under his direction at the Rockefeller Institute New York, was not available during the first year of the war, but after the failure in this country of anti meningococcic serum in the epidemic of 1915 the Rockefeller Institute reverted to the manufacture of the serum, and most generously placed a supply of a multivalent serum, made from 32 strains at the disposal of the Royal Navy [9] Other serums employed during this year, and not in the previous year, are Colonel Mervyn Gordon s various serums and the Pasteur Institute s multivalent serum In the early part of the second year of the war when the new serums were not available, Mulford s serum was given in a number of the cases and throughout the year use was also made of the Lister Institute serum and of Burroughs Wellcome and Co s serum

Of the 95 treated with intrathecal injections of serum 60 did not receive any other form of specific treatment, and had a mortality of 18 or 30 per cent, which is a little lower than that (31 6) of the 95 cases The remaining 35 cases received in addition one or more of the following forms of treatment hypodermic or intramuscular injection of the serum, of vaccines or of soamin or hexamine by the mouth with a mortality of 12 or 34 3 per cent In 23 out of the 35 cases the additional treatment was the simultaneous subcutaneous (or in a few instances intramuscular) injection of serum, this method was mainly adopted at Plymouth and Haslar, the mortality was 7, or 30 4 per cent Vaccines were given in 8 cases, but did not appear except perhaps in one or two instances to exert any decided beneficial effect The exact figures of the results of treatment are shown in the tabular form below —

Tabular Summary of Treatment

—	Cases	Deaths		Recoveries	
			Per cent		Per cent
Antimeningococcic serum— Intrathecally	95	30 or	31 6	65 or	68 4
Alone	60	18	30	42	70
Combined with serum hypodermically vaccines soamin or hexamine	35	12	34 3	23	65 7

Soamin— Alone	1	1		—	
Combined with intrathecal injections of serum Nec vide above	3	1		2	
Lumbar puncture only	6	4	66 7	2	33 3
Symptomatic treatment only	2	[illegible]		—	

More than three quarters of the 95 cases received serum within the first three days of the disease From tabulation of 1211 cases Flexner found that when the serum was given within the first three days the mortality rate was 18 per cent when between the fourth and seventh days 27 3 per cent and when later than the seventh day 36 5 per cent and therefore laid stress on the importance of early injection In the 95 cases treated with serum in the Royal Navy the influence of time can also be seen —

	Cases	Deaths	Recoveries
1st to 3rd day	[illegible]	22 or 29 7 p c	52 or 70 3 p c
4th to 7th day	1[illegible]	5 33 3	10 66 7
Later than the 7th	6	3 [illegible]	3 [illegible]

The results obtained by the use of the various brands of serum are shown below in a tabular statement Flexner's serum was employed in 39 cases altogether, with a mortality of 9, or 23 per cent , in 27 of the 39 cases it was the only serum used, with a mortality of 6, or 22 per cent , the 12 other cases in which other serums were given as well showed a mortality of 3 or 25 per cent The other serums were given in much fewer cases The mortality percentage of the 14 cases that received Burroughs Wellcome and Co 's brand (alone or combined with other serums) was slightly lower than that of the cases treated with Flexner's serum , and the 16 cases treated by Gordon's various serums alone showed an even lower mortality,

Table showing Results of Treatment by Different Serums

—	Cases	Deaths	Recoveries
		Per cent	Per cent
Flexner's serum alone	27	6 or 22·3	21 or 77 7
Combined with other serums	12	3 25	9 75
	39	9 or 23	30 or 77
Gordon's serums alone ..	16	3 or 18 7	13 or 81 3
Combined with other serums ..	6	3 50	3 50

	14	3 or 21 4	11 or 78 5
Mulford's serum alone ..	10	5 or 50	5 or 50
Combined with other serums	2	1	1
	12	6	6
Lister Institute's multivalent serum alone ..	11	6 or 54 5	5 or 45 5

The number of occasions on which serum was given intrathecally varied in the 95 cases from 1 to 8 according to the duration of the symptoms In some instances the improvement and fall of temperature after the injection of serum were dramatic.

Sixteen cases received one dose only, and 7 proved fatal, 6 being very acute or fulminating cases, 25 received two doses of serum (8 deaths), 22 cases three doses (7 deaths), 8 cases four doses (1 death), 11 cases five doses (4 deaths), 5 cases six doses (2 deaths), 4 cases seven doses (1 death), and 4 cases eight doses (no death) In many cases lumbar puncture was performed more often than serum was injected, in 1 chronic case in which serum was given six times, lumbar puncture was performed on 20 occasions

Serum rashes, erythematous or urticarial were mentioned in 22 or 23 per cent., of the 95 cases treated by serum but may have been more frequent The rashes and articular manifestations were practically confined to cases treated with Flexner's and Burroughs Wellcome and Co 's brands

Out of the 22 cases 21 received either Flexner's or Burroughs Wellcome and Co 's serum, 12 had Flexner's serum alone, 2 Flexner's and Gordon's serum, 1 Flexner's and the Pasteur Institute's multivalent serums 2 Burroughs Wellcome and Co 's serum alone, 1 Burroughs Wellcome and Co 's and Gordon's serums, and 3 Flexner's and Burroughs Wellcome and Co 's serum (only 4 cases had this combination) The remaining case had 70 c c of Gordon's serum, and did not have any manifestations of serum disease except the rash Out of the 95 cases treated with serum, 41 had Flexner's or Burroughs Wellcome and Co 's serum, and among them rashes occurred in 21 or 51 per cent , whereas among the remaining 54 cases treated by serum there was a rash in one case only Six of the 22 cases with rashes also had serum hypodermically The average amount of serum received by the cases with rashes was 65 c c , and the average amount received by 14 other cases which had Flexner's or Burroughs Wellcome and Co 's serum and recovered was 70 c c , or practically the same

On an average the rash appeared ten days after the first injection of serum In a case at Haslar which received one injection of 20 c c of Flexner's serum in a relapse seven weeks after the primary attack in Egypt, there was within a few hours an ' immediate ' serum rash The patient stated that nine lumbar punctures had been performed in the primary attack, but there is no official information as to the administration of serum

Of the 22 cases none proved fatal, but as the serum rash occurs after an interval of about ten days, the fulminating and acute cases are obviously excluded, and this observation has no prognostic value Six cases had both herpes and a serum rash , 9 cases an initial rash and a serum rash , and 3 cases an initial rash, herpes and a serum rash (in one case on two occasions), presumably in these instances the skin was especially prone to react

In some cases pains in the joints without effusion accompanied the serum rash, and in two instances effusion into the joints and a temperature of 102° coincided with the rash In 2 cases at Chatham temporary deafness occurred at the same time as a serum rash and arthralgia, and was regarded by Temporary Surgeon A C McAllister as a manifestation of serum disease

Grave accidents due to intrathecal injection of antimeningococcic serum were very rare

In one case lumbar puncture was done directly after admission to the Royal Naval Hospital, Plymouth and 50 c c of turbid fluid containing meningococci spurted out, 15 c c of Gordon's multivalent serum was given intrathecally and the same quantity hypodermically Respiration stopped at once The necropsy showed fibrinous adhesions and purulent streaks over the cerebral sulci, with but little exudation at the base of the brain Both lateral ventricles were distended with blood stained serum The purulent exudate over the hemispheres suggested that the illness had last a week In another case at Plymouth lumbar puncture on the third day of the disease gave exit to 30 c c of turbid fluid, and 15 c c of Gordon's multivalent serum were injected intrathecally , five hours later respiration stopped before the pulse The necropsy showed fibrinopurulent exudate over the base of the brain and much yellowish fibrin over the pons and medulla, turbid and blood stained fluid in both ventricles, œdema of the cerebellum pressing on the pons, dilatation of the right side of the heart, and recent and old endocarditis of the mitral valve Although death did not occur until five hours after the injection of serum, this case resembles the first in the presence of blood stained fluid in the lateral ventricles of the brain In a third case death occurred suddenly seven hours after injection of serum and the necropsy showed distension of the lateral ventricles and acute congestion and œdema of the cerebellum pressing on the pons

In a man who had had six lumbar punctures the site of the punctures became inflamed and death rapidly followed , at the necropsy it was found that the lateral ventricles were greatly distended with pus swarming with streptococci

In 2 cases lumbar puncture gave rise repeatedly to severe headache, which was partially relieved when serum was injected intrathecally

FOUR CASES OF HEMIPLEGIA CAUSED BY EMBOLISM FOLLOWING GUNSHOT WOUNDS OF THE CAROTID ARTERIES

By L COLLEDGE M B Cantab , F R C S Eng ,
CAPTAIN R.A.M.C (T F)
AND
JOHN SHAW DUNN, M D , Ch B Glasg ,
LIEUTENANT R.A.M.C (T C)

A SERIES of 14 cases has recently been reported by Sir George Makins[1] in which symptoms of cerebral embolism followed gunshot injury of the carotid arteries Of these cases only one ended fatally, and in it a post-mortem examination was not available, so that a complete anatomical account of the conditions could not be obtained Four similar cases, presenting the remarkable clinical picture of a wound in the neck accompanied by hemiplegia and loss of consciousness, and all ending fatally, have come under observation in a casualty clearing station As a necropsy was performed in every case they appear worthy of record

CASE 1 —In this case there was a small wound on the left side of the neck, below and behind the angle of the jaw , the exit wound was also on the left side, lower down, about 1¾ inches from the middle line behind An extensive diffuse swelling appeared behind the angle of the jaw , this

---

[1] The Lancet 1916 ii 543

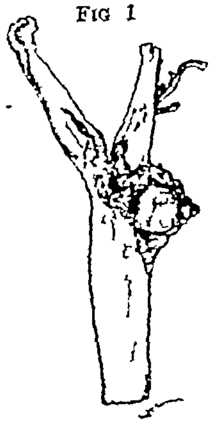
swelling did not pulsate, nor was there any *bruit* The patient was unconscious and stertorous, and there was hemiplegia affecting the face, arm, and leg on the right side The patient died about 26 hours after being wounded

On dissection of the left side *of the neck there* was noted a localised swelling with hæmorrhage, on the walls of the external and internal carotid arteries, just above the bifurcation of the common trunk Two small wounds, with ragged edges, were present, *one on the front* of the external and the other on the back of *the internal artery*, *these appeared to* be sealed up by firm red thrombus which was *entangled* in projecting shreds of the adventitial tunics, and the thrombus on the back of the inner vessel exhibited a firm pea like projection backwards A probe which was readily passed, with light pressure, in at one opening and out at the other evidently traversed the lumina of both arteries The vessels were *removed* unopened, the internal carotid being cut across half an inch *from the base of* the skull Its lumen was patent at that level, *but* was filled by thrombus *to a* point just below When fluid was poured into the common carotid artery it was observed to make its exit by the external artery, none escaping by the wounds *The lumen of* the left internal carotid artery was observed to be patent also at the *point* where it was cut in removing the brain The *left* middle cerebral vessel was normal to a point just *beyond the origin of its perforating branches*, but was there distended and completely blocked by a red adherent thrombus The *Bacillus perfringens* was present in this clot in considerable numbers There was a well marked condition of early softening of the left hemisphere of the brain, excepting the occipital and frontal lobes The basal nuclei were normal

CASE 2—In the second case there were multiple small bomb wounds, one of which was on the right side of the *neck* posteriorly There was a similar non pulsatile swelling of the neck, and the symptoms produced were similar *to those in the first case* The patient died, hemiplegic *on the left side about* 18 hours after being hit

On post mortem examination much effused blood was present in the tissues of the right side of the neck The missile, a small *fragment of* bomb-casing, was seen lying under the right sterno thyroid muscle having penetrated the right lobe of the thyroid gland *There* was a *false* aneurysm, about an inch in diameter, on the deep internal aspect of the right common carotid artery, its wall was *formed of firm fibrin* mixed with blood corpuscles On slitting up the *vessel after* removal, a linear wound, ⅝ inch in length, was seen on its posterior and inner wall about 1½ inches below the bifurcation A firm cylindrical thrombus was adherent to the upper end of this wound and extended upwards for a distance of 1¼ inches, lying free in the lumen and *only* partially filling it The *external and* internal carotids were free of thrombus as far as they could be traced in the neck, and the latter was patent also at the point where it was cut inside the skull in removing the brain The right Sylvian artery was completely occluded by firm red thrombus just beyond the origin of its perforating branches The right hemisphere of the brain showed well marked early softening, with the exception of the frontal and occipital poles The grey matter was swollen, red and œdematous and had a blurred margin, and contrasted with the normal left side The basal nuclei were intact

FIG 1

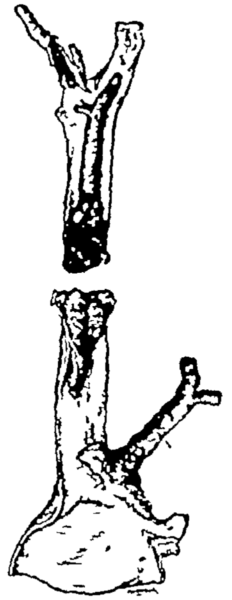


The carotid arteries from Case 3, showing the false aneurysm and the thrombi inside the vessels The perforation in the wall of the external carotid is quite obscured by thrombus

CASE 3—This case was admitted within six hours of being wounded with the same symptoms of stertor and hemiplegia The patient had been shot through the neck from side to side On the right side there was a small wound near the posterior border of the sterno-mastoid muscle, about midway between its attachments Arterial blood escaped freely from this wound when the dressing was removed The right common carotid was therefore ligatured just above the omo hyoid, the hæmorrhage was thereby arrested The patient died without any alteration in the symptoms within 15 hours of being wounded

In this case a false aneurysm about the size of a walnut was found on the back of the right external carotid artery just above the bifurcation of the main trunk (Fig 1) A small perforation about ⅛ inch in diameter was present in the posterior wall of the vessel at that level The edges of this wound were ragged and bruised, and the opening was crossed by some residual strands of adventitia with clot adherent to them The posterior wall of the internal carotid artery was much bruised at a slightly lower level but was not *perforated* *Fairly firm greyish pink thrombus* was adherent on the walls of the common carotid artery at its bifurcation, and extended ½ inch upwards in the lumen of the internal and 1¼ inches in that of the external vessel being firmly attached over the bruised areas of intima. The external carotid was the only vessel completely occluded by thrombus Emboli were present in several branches of this vessel in the neck, the lumen of the internal carotid was free of clot from just above the injury on its wall to its termination inside the skull The right middle cerebral vessel was normal at its origin, but all the larger branches in the Sylvian fissure were filled by portions of thrombus of the same consistence as that seen in the large vessels in the neck The island of Reil and the motor area of the right cerebral hemisphere were softened and much congested, while the basal nuclei and the poles of the hemisphere remained normal A few streptococci were present in films from the thrombi, and a few colonies were obtained on cultivation

FIG 2



Illustrates the complete separation of the common carotid artery and the sealing of the ends by thrombus The shape and arrangement of the thrombi indicate that they have formed while the blood was still circulating

CASE 4—This case was admitted about six hours after being wounded, already in the same condition, stertorous, and with hemiplegia affecting the face, arm, and leg on the right side There was a wound on the left side of the neck about 2½ inches above the clavicle This patient survived for about *72 hours* after being wounded

Post mortem the left common carotid artery was found to be completely severed and the ends, filled with thrombus were retracted so as to leave a gap half an inch in length (Fig 2) The ends of the vessel were much bruised and some laceration was present for half an inch upwards on the walls of the upper segment The thrombus in the lower segment was traced downwards to within an inch of the aorta, that in the upper extended up to the bifurcation of the common carotid, and thence for a considerable distance into the external carotid and its branches and for half an inch only into the internal carotid The lumen of the latter vessel was patent above that level On the base of the brain the left Sylvian artery was plugged by firm red thrombus beyond the origins of the perforating branches This had given rise to cerebral softening, as in the previous cases

In each of these cases the hemiplegia and cerebral disturbance were caused by occlusion of the middle cerebral artery or its branches In all four there was thrombus present in the carotid arteries in the neck, consequent on damage of the arterial walls and in each there were several inches of the internal carotid artery patent between that thrombus and the portion blocking the cerebral vessel It is consequently a justifiable conclusion that the blood continued to flow for a time at least in the wounded vessels and that the occlusion of the cerebral arteries occurred by embolism Similar emboli were found in one instance in the branches of the external carotid also

The damage to the large cervical arteries was in every case considerable In three there was actual perforation of the wall, in the fourth the trunk was found completely severed but this no doubt occurred secondarily by sloughing after the vessel was fully thrombosed It is remarkable that hæmorrhage was so slight in these cases, in only one of them was ligature necessary

Sir George Makins draws attention to the tardy development and partial nature of the paresis as outstanding features in his series, and contrasts this with the prompt and complete hemiplegia, followed by a fatal issue in 24 to 36 hours which may occur after ligature of the common carotid artery In the four cases related, however, the early appearance and completeness of the hemiplegia and the rapidly fatal issue resemble the effects of ligature of the common carotid It is natural that such cases, only surviving from 15 to 72 hours, would not reach a base hospital

We are indebted to the Medical Research Committee for permission to make use of the two drawings by Mr A K. Maxwell

ON THE PRESENCE OF AN ACCESSORY FOOD FACTOR IN THE NASAL SECRETION

AND ITS ACTION ON THE GROWTH OF THE MENINGOCOCCUS AND OTHER PATHOGENIC BACTERIA

(*Preliminary Paper*)

BY CRESSWELL SHEARER, M D, F R S,
MILITARY HOSPITAL, DEVONPORT

(*Report to the Medical Research Committee*)

1 *Introduction*

IN dealing with numbers of cerebro-spinal fever contacts during the recent epidemic it was noticed that the growth of the meningococcus was in some instances strongly influenced by the amount of nasal secretion transferred by the swab to the surface of the culture medium. It was found from experiment that if a trace of dilute sterile nasal secretion was added to the surface of the culture medium, it brought about a rapid growth of the meningococcus when this medium was subsequently inoculated with this germ The growth is always many times the amount obtained on the same medium, on planting out a similar quantity of culture, in the absence of nasal secretion [1]

The action of sterile dilute nasal secretion in accelerating the growth of the meningococcus would seem to be entirely in the nature of an accessory food body or vitamine as alone this secretion is quite incapable of supporting or stimulating the growth of this germ This conclusion is supported by its peculiar properties It is soluble in water, slightly soluble in alcohol, and almost insoluble in ether [2] It has great heat-resisting capacity, withstanding autoclaving at 120° C and boiling in strong hydrochloric acid for 12 hours without losing strength On filtration it always undergoes considerable adsorption, even when passed through an ordinary filter paper, and it almost entirely disappears from any fluid when this is passed through a Doulton filter candle All chemical manipulation, drying, precipitation, &c. appreciably weaken its power of stimulating the growth of the meningococcus

In addition to the meningococcus and its allies it has been shown to accelerate the growth of the pneumococcus *B typhosus*, *B coli communis*, various fæcal streptococci, and a number of throat bacteria. It is highly probable that it will accelerate the growth of all pathogenic bacteria when added in sterile fashion to any suitable culture material, whether solid or fluid [3]

2 *Mode of Collection of Nasal Secretion*

The nasal secretion used in the following experiments was obtained either by collection direct from the naso pharynx by means of a suction pump, or by the employment of naso-pharyngeal swabs such as those used in the routine swabbing of cerebro-spinal fever contacts. This latter method proved the most convenient These swabs are made of ether washed cotton wool placed on the ends of flexible wires which are introduced into the naso pharyngeal region through the mouth retracted within bent glass tubes, so that all contamination from the oral secretion is avoided The swabs were then extracted in distilled water It was found that quite a considerable amount of secretion could be obtained in this way This will be referred to in the following experiments as "dilute" nasal secretion in distinction to that collected "undilute" direct from the mucous membrane of the naso-pharynx, by means of the pump

3 *The Preparation of Various Extracts of Nasal Secretion* [4]

(*a*) General treatment in the preparation of aqueous, alcoholic and ethereal extracts. The cotton-wool was removed from the swab wires and covered with the solvent in glass stoppered specimen tubes of suitable size, using 1–2 c c for each swab After standing for 24 to 48 hours, the liquid was removed with a pipette and filtered through a 5 c c Swedish acid extracted filter paper Aqueous extracts which were further treated, and all alcoholic and ethereal extracts, were evaporated to dryness on a tepid water bath at a temperature of about 60° C, the basin being removed before it was absolutely dry when water was the solvent, and then taken up in distilled water, 1 c c of water being allowed for each swab extracted

(*b*) Preparation of hydrolysed nasal secretion 3 c c of undilute nasal slime was heated with ten times its volume of strong HCl in a test-tube standing in boiling water for six hours More HCl was added to make up for the loss by evaporation, and the heating continued for six hours more The solution, which was faintly yellow, was transferred to a porcelain dish and the excess of acid was evaporated off on the water bath with the continual addition of water When nearly all the acid had been removed the remainder was dried at a low temperature, dissolved in 7 c.c. of water, and made faintly alkaline to litmus paper with N/10 NaOH, about 5 c c being necessary

All the extracts before being sealed up in vaccine tubes were tested and their alkalinity adjusted as closely as possible to Ph = 7 35 of Sorensen's scale The extracts after being sealed up were finally sterilised at 55° C for an hour All manipulation of the extract was conducted in beakers of Jena glass, or Berlin porcelain or platinum, and great care was taken to have all glassware, especially the slides used for mixing the dilutions clean and free from any chemicals The distilled water used was redistilled from glass several times

4 *Method of Testing the Action of Extracts*

The action of the various extracts of nasal secretion in stimulating the growth of the meningococcus and other bacteria was tested by making a number of dilutions of the germ in the extract and planting out each dilution separately and comparing their growth, with a similar quantity of the same emulsion diluted in a similar manner in distilled water or Ringer's solution, and planted out in the same way It was found after several trials that distilled water offered the best form of control In the following experiments care was always taken to make the control dilution first and to plant it out immediately Thus all harmful action of distilled water on the germ was minimised as much as possible [5] Where typhoid and coli organisms were used all emulsions and controls were made in Ringer's solution

A large number of methods of dilution were tried. The one found most useful consisted in taking up in a calibrated pipette, finely throttled to ensure accurate measurement, nine volumes of the fluid to be tested, each volume representing 25 c.mm. of liquid They were then spread out separately on sterile slides Then with a smaller pipette, also throttled, 5 c mm of a standard emulsion [6] of the meningococcus (5000 million to the c c.) in Ringer's solution, was drawn up This was added to the first of the 25 c mm volumes on the slide and thoroughly mixed by drawing it up to a fixed mark each time in the process of mixing Then from this 5 c mm was taken up and transferred to the second 25 c mm volume and the mixing repeated This procedure was gone through in succession with each of the nine volumes Thus in the end a series of nine successive dilutions of the germ were obtained Then by means of a fine sterile camel hair brush or fine capillary tube, a certain quantity of each dilution was transferred in turn to the surface of the culture medium, commencing with the highest and gradually working down to the lowest dilution The quantity transferred could be accurately measured when a capillary tube was used, but when a brush was employed it was only roughly the same in each instance The dilutions were spread on the surface of the culture medium by dipping the brush in one of them and then drawing it rapidly across the surface of the plate This operation was repeated in turn with each of the dilutions Thus a series of nine parallel lines were obtained on the plate, each representing a particular dilution of the germ in the solution to be tested[*]

---

[1] If sterile dilute nasal secretion be tested against the action of sterile dilute oral saliva in stimulating the growth of the meningococcus, it will be found that oral secretion has also some power in this respect, but this is much less than with nasal secretion Gordon has shown (Brit Med Jour June 17th 1916, p 849) that in the unsterile state oral saliva has a marked inhibiting action on the growth of this germ When the various mouth bacteria were removed from this secretion by sterilisation or the centrifuge this inhibiting action immediately disappeared

[2] It can be precipitated with phosphotungstic acid and neutral lead acetate but this needs further confirmation

[3] In the experiments described in the present paper the medium used is Crowe's "chocolate medium" (see THE LANCET Nov 20th 1915) In other experiments similar results have been obtained with Gordon's legumen trypagar

[4] For the proper preparation of the extracts the Medical Research Committee have kindly placed the services of Mr D Matthews at my disposal

[5] I have shown elsewhere (THE LANCET 1916, ii 902) that the meningococcus is peculiarly resistant to the hypotonic action of distilled water I have shown that it can withstand its action for many hours without experiencing any apparent ill-effect.

[6] In speaking of a "standard emulsion" of the meningococcus in the following experiments it will always be understood that one in Ringer's solution of the strength of 5 000 000,000 cocci to the cubic centimetre is meant

5 *Experiments*

Experiment I[†] (Figs 1 and 2) —A "standard" emulsion of an old laboratory culture of meningococcus (Littledale) was made up in Ringer's solution 5 c mm of this emulsion was added to 25 c mm of distilled water and of an aqueous extract (see under Sec 3*a*) of dilute nasal secretion respectively, and diluted down through nine successive dilutions, and planted out by means of a brush as described under Sec 4 Thus nine parallel lines, as shown in Figs 1 and 2 were obtained on the plates,[‡] one representing the dilution in nasal secretion extract and the other the control dilution in distilled water Line No 1 contains the fewest number of germs while line 9 contains the largest number Each line contains very roughly the same number of germs as the corresponding line on the other plate The plates were incubated at 37° C for 24 hours and then taken out and the resulting growth photographed The photographs show the plates reduced to half natural size

In Fig 1 showing the dilution in distilled water, little growth has taken place except on lines 7 8, and 9 In the same degree of dilution in aqueous extract of dilute nasal secretion Fig 2, considerable growth has taken place on all the lines and is confluent in the case of lines 7, 8, and 9 A comparison of the two photographs gives a rough idea of the accelerating action of nasal secretion on the growth of the meningococcus

It was immaterial whether in this experiment, Ringer's solution was substituted for distilled water in the control dilutions to obviate all possible harmful action of the distilled water, the result was the same There is possibly a slight increase in the growth obtained in the control, due to the use of Ringer's solution but this increase was not sufficient to alter the main result of the experiment There was always a preponderating growth with nasal secretion extract

Experiment II (Figs 3 and 4) —In this experiment, *instead of an old laboratory culture being used as in Experiment I, a freshly isolated strain of the meningococcus (Walters) was taken* This had been obtained from the spinal canal of a cerebro spinal fever patient about a week previous In this instance the dilutions of a "standard" emulsion were made as before in distilled water and nasal secretion (aqueous extract) but instead of a small quantity of each dilution being transferred to the plates by means of a brush each dilution containing 30 c mm of fluid was transferred by means of a fine capillary pipette to the surface of the culture medium Thus instead of a series of lines a series of drops or blebs were obtained representing 11 consecutive dilutions of the germ in distilled water and nasal extract respectively

A comparison of Figs 3 and 4 shows the accelerating action of the nasal secretion extract over that of the distilled water one The figures, however, hardly bring out the proper difference between them as the spreading of the drops on the surface of the medium has been irregular Actual inspection of the plate Fig 4 shows for instance that dilution No 11, which contains the fewest number of organisms, is very thin and spread out, while No 1, which contains the largest number of germs, is very heaped up and thick a condition which is not very obvious from the photograph

The comparison of dilutions 7-11 of Fig 4 with the same dilutions in Fig 3 dispels any doubts as to the accelerating action again of nasal secretion in this experiment

Experiment III —In this experiment *it was sought to find out the amount of accelerating action nasal secretion extract brought about on the growth of the meningococcus when growing in a fluid broth medium and not a solid medium as in the former experiments* To two small vaccine tubes containing each 2 c c of sterile glucose litmus broth 5 c cm of "standard" emulsion of meningococci (Walters) was added To one of the tubes in addition 5 c cm of an aqueous extract of dilute nasal secretion was added The tubes were then incubated for 48 hours at 37° C At the end of this time the tube that had received the nasal secretion in addition to the meningococci had entirely lost all trace of pigment, while that which was without the extract still retained a certain amount of reddened litmus pigment The tubes were then carefully shaken up to ensure an even distribution of the cocci, and counts were made of a certain volume of fluid from each tube This showed that there was roughly eight times the number of cocci per c mm in the tube with the nasal extract as compared with that without it

Experiment IV —In this experiment an attempt was made *to see if prolonged boiling of aqueous extract of dilute nasal secretion had any action in destroying its power to stimulate the growth of the meningococcus* 4 c c of an aqueous extract of dilute nasal secretion was boiled continuously for five hours distilled water being added from time to time to keep it at the same volume (See Sec 3 *b*) It was then tried out as before against some of the same aqueous extract unboiled, with a "standard" emulsion of meningococcus (Littledale) It was found that the boiling had had but little or no effect in weakening the action of the nasal secretion

Experiment V (Figs 5 6, and 7)—In this experiment *hydrolysed nasal secretion prepared by boiling undilute nasal slime with strong hydrochloric acid for 12 hours (as described in Sec 3 (b)) was tested against the action of the same nasal secretion untreated with HCl* Dilutions of a "standard" emulsion of a freshly isolated culture of meningococcus (Lake) were made in distilled water (control), nasal slime and nasal slime hydrolysed, respectively These were planted out on a plate by means of a brush in the usual way

Photographs 5-7 show the result of this experiment It will be seen that the hydrolysed nasal secretion is as active in accelerating the growth of the meningococcus as the same secretion untreated (Figs 6 and 7) The action of both hydrolysed and the non hydrolysed secretion in accelerating growth is well shown by comparison of these plates with that planted out with the control dilutions in distilled water This experiment has been repeated a number of times with different strains of meningococci and always gave the same result

Experiment VI (Figs 8-11) —*To determine the relative power of a plain alcoholic extract of dilute nasal secretion as compared with a plain aqueous extract and an ether extract of the same in stimulating the growth of the meningococcus* Dilutions of a standard emulsion of meningococcus (Lake) were made as before The diluents were distilled water (control) aqueous extract of dilute nasal secretion plain alcoholic extract of dilute nasal secretion and ether extract of the same Figs 8 11 show the resulting growth obtained after 24 hours incubation at 37° C Comparison of Fig 10 with Fig 9 shows the action of a plain alcoholic extract of dilute nasal secretion to be almost as active as that of an aqueous one while comparison of both these figures with the control in distilled water (Fig 8) shows the amount of acceleration in growth produced

The conclusion drawn from this experiment was that the active principle in nasal secretion which [illegible]

---

[*] If we commence with an emulsion of 5000 million meningococci to a cubic centimetre and make nine consecutive dilutions of 5 parts in 30 in each dilution then theoretically we should expect to find in each of the nine dilutions the number of cocci per cubic centimetre as follows —

Dilution	Cocci	Dilution	Cocci
1	833 000 000	6	107 000
2	139 000 000	7	18 000
3	23 000 000	8	3 000
4	4 000 000	9	500
5	640 000		

These numbers were never actually approached in the following experiment as the pipettes and brushes were not sterilised in passing from one dilution to another

[†] The numbering of the experiments is only for the convenience of the present paper many of the experiments described have been repeated a great many times

[‡] All the experiments described in this paper refer to implantations on Crowe's alkaline medium

EXPERIMENT VII —*B typhosus*

12

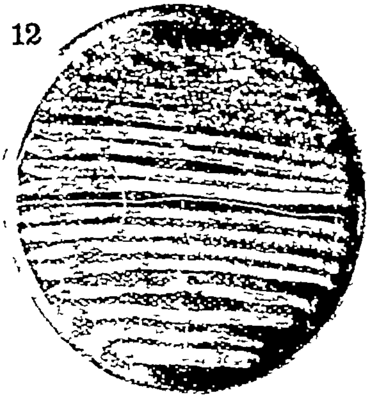

FIG 12.—Showing the action of dilute nasal secretion in stimulating the growth of *B typhosus* The upper half of the plate shows the dilutions of the germ in Ringer's solution while the lower half shows the dilutions in dilute aqueous extract of nasal secretion

Cultures (one third natural size) photographed after 24 hours' growth The streaks are to be read from above downwards growth of the meningococcus is soluble in distilled water, less so in alcohol and almost insoluble in ether

Experiment VII (Fig 12) —*To determine the action of nasal secretion extract on the growth of B typhosus* In Fig 12 the upper half of the plate has been planted out in the usual way with dilutions of an emulsion of *B typhosus* in Ringer s solution, in the lower half, with dilutions of the same emulsion in aqueous extract of dilute nasal secretion Fig 12 shows that a much more abundant growth took place on that half of the plate which received the nasal secretion

The conclusion drawn from this experiment was that the growth of *B typhosus* is accelerated in a similar manner to that of the meningococcus by an aqueous extract of dilute nasal secretion

Similar results were obtained in experiments with the following germs —*Streptococcus zymogenes*, *Micrococcus pharyngeus flavus*, pneumococcus and *B coli communis*

Conclusion

The outstanding results of the foregoing experiments show that in nasal secretion there is present some body which greatly accelerates the growth of the meningococcus on an artificial culture medium Alone it is incapable of acting as a food or stimulant to the growth of this germ It is soluble in water less so in alcohol, and very insoluble in ether It has great heat-resisting power, being able to resist prolonged boiling for many hours It is not destroyed by boiling in the presence of strong hydrochloric acid for twelve hours In addition to the meningococcus it also stimulates the growth of many other pathogenic germs

---

A NOTE ON THE CAUSE AND PREVENTION OF TRENCH FOOT

BY C NEPEAN LONGRIDGE, M D VICT F R C S ENG, M R C P LOND,

LIEUTENANT ROYAL ARMY MEDICAL CORPS

No one who has had an opportunity of observing many cases of trench foot particularly in the later stages of the disease can have failed to be struck with certain characteristics presented by it The lesions are indolent slow to heal and prone to break down again on the slightest provocation The scar tissue formed is weak and ulcerates easily Indeed, the whole picture of the disease reminds one irresistibly of the trophic sores appertaining to diseases of the central nervous system I wish to set forth in this paper my reasons for thinking that trench foot is an affection of a trophic nature

Some three years ago a book on electro pathology was published by Mr A E Baines a distinguished electrical engineer Space does not permit me to give an account of the far reaching vista of promise which this little known work has opened up to medicine An abler pen than mine has recently put the whole matter before the profession Let it suffice to say that Mr Baines believes that the brain and possibly the cord, is the seat of electrical generation, and that the current so generated is carried to the tissues by means of the nerves, which to the electrician s view are nothing but insulated cables Here we have the trophic influence of physiology and medicine that vague generalisation which from our student days we have been content to accept without questioning Mr Baines has shown us how to measure and modify this trophic influence, and I venture to predict that in the future his name and fame will equal that of those illustrious ones Simpson, Lister and Koch as benefactors of the human race This is no mere discovery of an isolated fact in medicine Many a patient worker has given his brick, his hard wrought stone of research to the building of the sacred fane of Æsculapius As is perhaps fitting and proper for an engineer Mr Baines has come and shed a flood of light in our temple For he has given us a fundamental principle

The dominating factor in the conditions under which trench foot occurs is wet When a man is standing for days on end in water and liquid mud his boots socks and the skin of his feet and legs become soaked As is well known the electrical resistance of the skin is enormously diminished when the skin is wet Under these conditions a gradual leakage of electricity to earth takes place from the feet Other things being equal electricity will always leak from a point in preference to a plane surface which accounts for the fact that the toes are most affected This leakage deprives the cells of the foot tissues of their trophic influence and they die Hence the lesions of trench foot

Local leaks of electricity may be detected by a suitable galvanometer One pole of the galvanometer should be connected to a silver plate about the size of a florin which is fixed in the centre of the patient s forehead, there is no special reason for fixing it on the forehead except that it is the most convenient spot in the middle line of the body The other pole is connected to a contact plate mounted in an insulated handle so that the contact or electrode can be placed on any portion of the body it is desired to test Before testing it is necessary to "earth" the patient in order to dissipate any induced charge of electricity of which he may be the host If this is not done the patient s own intrinsic current may be swamped by charges he has picked up from trams, electric trains or other sources With both poles in contact with the body the galvanometer will give a deflection When leakage is taking place from any particular area a high and rapid deflection is noted I have been examining and treating various cases on Baines s principles for a matter of about two years and have found such a leakage taking place from the feet and legs of soldiers suffering from trench foot whom I had under my care last spring Moreover the results I obtained by treating these cases by dielectric oil were better than the results obtained by any other method I tried I also made a few experiments bearing on this subject

Experiment 1 —With the aid of Miss Flecker, at the Ladies' College Physical Laboratory, Cheltenham, I estimated the electrical resistance of a piece of oak tanned sole leather 3 inches long by 1 inch wide We found that when dry the resistance was practically infinity When wet the resistance is that of the fluid the leather has soaked in

Experiment 2 —One pole of the galvanometer was connected to an electrode which could be held in the hand The other pole was connected by an insulated cable to a copper plate imbedded in the earth Another insulated cable was connected at one end to the metal pipe supplying water to the house, and at the other end to a brass rod of 1 inch section After earthing myself I held the brass rod in one hand and the electrode in the other, and obtained a rapid off scale deflection, showing firstly, that an electric current was coming from my body, and secondly, that the earth connexions were working properly, for the current passed out by one hand through the brass tube to the water pipe thence about 20 feet through the earth to the copper plate and through the galvanometer to the other hand, so completing the circuit

Experiment 3 —The brass tube was then laid on the floor which was covered by a thick carpet I held the electrode by one hand and put both feet on the brass tube I wore ordinary boots which were dry No deflection was obtained because the dry leather soles of my boots insulated me from the earth I then took my boots off and put my bare feet on the tube and obtained an off scale deflection

Experiment 4 —Next day was wet and I walked about half a mile so that the soles of my boots which were free from holes and metal nails became wet On holding the electrode in one hand and placing my feet on the brass tube, a rapid off scale deflection occurred showing that current was passing through my boots to earth

Experiment 5 —The pole of the galvanometer connected to earth by the copper plate was disconnected It was reconnected to a hand electrode exactly like the one previously used so that the galvanometer was now connected to the hand electrodes only After the necessary earthing process, I held the electrodes in the hands and obtained a deflection which remained steady at 170 mm I then placed my feet still in wet boots on the brass tube and awaited results The light on the scale very slowly began to recede towards zero I repeated this experiment several times The light never remained at zero but if it got as far went over to the other side of the scale, and generally registered 40 to 60 mm I take this as evidence that electricity was gradually leaking out of my body to earth, through my wet feet One would not expect the light to register zero as there is continuous generation of electricity in the body In view of these experiments, the grandmotherly advice we have so often received not to stand about in wet boots takes on a new and important significance which ought to claim our belated respect They also to my mind afford evidence that trench foot is probably caused by long-continued leakage of electricity from the feet

I noted that Dr Leonard Hill had advocated rubber boots and greasing of the feet for the prevention of the disorder recommendations with which I cordially agree I sent to him in the spring a note about my own experiments and received from him a courteous letter thanking me for my "ingenious speculations," but countering me with the query "What about fishes, fishermen, and Channel swimmers?' When truth is really truth the most knock out objections often end in being pillars in its support Just as the vagaries of radium appeared to undermine the whole structure of physical science, and now form an additional proof that the foundations of that science have been well and truly laid, so Dr Hill's objections assist my argument. For fishes are provided with a dielectric coat of mucous, I never heard of fishermen who had wet feet as long as the men in the trenches and Channel swimmers always try to emulate the fish by rubbing themselves with a dielec ric coat of oil Their idea is to keep out the cold—it is really to keep in the electricity of their bodies, improved methods of accomplishing this result will at once suggest themselves to anyone acquainted with Baines's work.

The experience of officers at the front is that trench foot can be prevented. I am certain it can, but it can only be done, firstly, by keeping out the wet, and, secondly, by keeping up the electrical resistance of the skin of the feet The feet should be thoroughly greased, and by far the best grease to use is the dielectric ointment which is now an article of commerce It is interesting to note that our French colleagues are suggesting the use of ambrine for trench feet, they have had very good results with it in burns, but it is used empirically without appreciation of its dielectric action I doubt if anything could improve on the results obtained by dielectric oil in cases of burns

Rubber boots if worn for any length of time cause the feet to perspire too freely White Robertson in the paper referred to above has shown that the soles of the feet and palms of the hands are parts which are designed to sweat freely and through which the normal escape of electricity to earth mostly takes place The disadvantage of rubber boots is that owing to the excessive perspiration they cause the skin of the feet is liable to become sodden and so lose its electrical resistance. Soaking the boots, socks and puttees in oil is the alternative I suggest for rubber boots Any thick oil would do as a preventive, kitchen fat rendered with olive oil or cotton seed oil might be tried, but I think that the skin of the feet should be rubbed with a dielectric grease. If signs of trench foot should develop in cases where these precautions have not been efficiently carried out the best treatment is to wrap the foot and the whole of the lower part of the limb as far as the knee joint in gamgee tissue soaked in dielectric oil I have seen enough of this treatment to justify the assertion that no serious case of trench foot necessitating amputation need take place

A CASE OF SARCOMA OF THE MEDIASTINUM INVADING THE LUNG

By A G M GRANT, M.D EDIN, D.P H.,
FIRST ASSISTANT MEDICAL OFFICER, WESTMORLAND SANATORIUM,
GRANGE-OVER-SANDS

THE following case illustrates the points of resemblance between phthisis and malignant disease of the lung On the admission of the patient to the sanatorium seven weeks before his death the clinical picture was in the main one of phthisis but in the later stages the distinguishing features of thoracic tumour manifested themselves and suggested malignancy

A man aged 55 years was admitted to the Westmorland Sanatorium on Sept 13th 1916 with a history of good health until the previous April when he first complained of radiating pain in the front of his chest followed shortly afterwards by cough and expectoration which compelled him to give up work in July His sputum was copious and mucopurulent, of a yellowish brown colour, and well intermingled with blood No T B were found Examination showed deficient expansion, dullness high pitched breath sounds almost tubular in character, and increased vocal resonance over the upper lobe of the right lung Over the apex of the right lower lobe the signs were somewhat similar but less pronounced The left lung seemed healthy There were no cardiac murmurs and the urine was normal His chief complaint was of the flitting pains across his chest, which were generally most severe at night Cyanosis, first noticed in the lobules of his ears early in October, gradually spread to the face, while there was none of the extremities With the deepening of the lividity there developed œdema His lower eyelids became heavy with watery bullæ and his neck swollen, measuring on the day of his death 17 inches at the level of the thyroid cartilage, while in health he wore a collar of 15¼ inches The external jugular veins stood out prominently The superficial veins of the chest became distended, more markedly on the left side, and running along the left costal margin corresponding to the attachment of the diaphragm was a network of dilated venules The superficial abdominal veins were not distended There was no swelling of the arms or legs The glands at the root of the neck and in the axillæ were enlarged The pupils were equal and so were the radial pulses Towards the end he became very drowsy, even falling asleep during conversation His breathing became stertorous and he died on Nov 1st A differential blood count made after the cyanosis became evident showed polynuclears 92 per cent lymphocytes 3 per cent, and mononuclears (large) 5 per cent The Arneth count gave a ratio of 46 to 54 The temperature was normal until the last few weeks, when there was a slight rise, but not beyond 99·4° F, with a small daily variation At the post-mortem examination it was found that a large solid mass filled the superior and the posterior mediastinum The pleura covering the right lung was firmly adherent The upper lobe of the right lung was almost entirely invaded by tumour, and there was involvement of the upper portion of the lower lobe The left lung and its pleura were healthy Microscopically the tumour was seen to be a lympho-sarcoma A section showed the growth destroying the wall of the superior vena cava and projecting into its lumen

The case is of interest in showing the difficulties attendant on the making of a diagnosis of phthisis in the absence of tubercle bacilli from the sputum The blood examination was helpful, although unfortunately, a count was not made until the later stages of the illness The high polynuclear count suggested an acute mixed infection if the case were really tuberculous, but the nearly normal temperature negatived such an infection The Arneth count was practically normal, while according to the findings of different observers an active tuberculosis causes a definite deviation to the left

For permission to publish this case I am indebted to Dr C F Walker, medical superintendent of the Westmorland Sanatorium

Grange-over-Sands

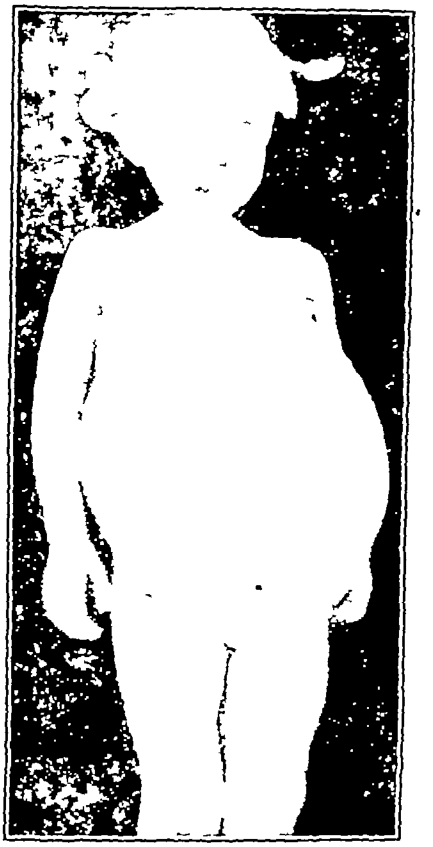
A CASE OF LARGE OMENTAL CYST IN A CHILD

By FREDERICK C PYBUS, M S DURH, F.R C S ENG.,
SURGEON TO THE HOSPITAL FOR SICK CHILDREN ASSISTANT
SURGEON TO THE ROYAL VICTORIA INFIRMARY
NEWCASTLE-ON TYNE.

OMENTAL cysts are sufficient rarities to warrant the publication of individual examples The following notes are those of a patient in the Hospital for Sick Children, Newcastle-on-Tyne

The patient, a girl, aged 4 years, was admitted to hospital in June, 1915 supposed to be suffering from tuberculous peritonitis She was the only living child of a family of three, the mother having died of phthisis It was noted that the child's abdomen had been swollen since she was 9 months old She had been tapped on two occasions at the ages of 18 months and 2 years, but on each occasion the fluid gradually returned After admission she was again tapped six pints of fluid being removed A few weeks later she developed scarlet fever and was transferred to the fever hospital The photograph shows the condition of the abdomen at this period

She was readmitted to the hospital in May, 1916 The circumference of the abdomen was 29¼ inches She was tapped twice shortly after admission, two pints being removed on each occasion The fluid was of a slightly reddish colour and contained cholesterin crystals I was then asked to see her by Dr J E Dainty, who suggested that the condition might be a cyst and that abdominal exploration would be advisable She was transferred to my ward and an operation was carried out in June, 1916 The abdomen was opened above the umbilicus A thin walled cyst was found occupying the larger part of the abdomen Three fine strands passed from the cyst to the abdominal wall, which I regarded as due to the previous aspirations The cyst was tapped and drawn outside the abdomen It was thin walled, partially loculated, and situated in the great omentum It was readily stripped from the omentum except at one part where the omentum was torn, and its upper part had to be peeled from the greater curvature of the stomach The omentum was repaired, completing the anterior wall of the lesser sac The abdomen was then closed The child made a perfect recovery and was discharged a fortnight later The cyst was of the size of a large football The exact quantity of fluid was not measured, but half filled an ordinary pail The cyst was occupied by a thin brownish fluid containing cholesterin crystals and was partially divided into several loculi Portions of the great omentum were removed with the cyst and remain adherent to its wall Microscopic examination of its wall revealed no epithelial layer, so that it is difficult to account for its origin



Omental cyst in a girl of 4 years Circumference of abdomen 29½ inches

Newcastle on Tyne

DONATIONS AND BEQUESTS —The Chelsea Hospital for Women has received from the trustees of the Zunz Bequest £5000 being the balance of the £10 000 generously promised by the trustees towards the rebuilding of the hospital —The trustees of the late Miss Marjory Shanks Schaw of Glasgow have given £60 000 to the Western Infirmary £40 000 to the Victoria Infirmary Glasgow and £10 000 each to the Royal Samaritan Hospital for Women the Royal Hospital for Sick Children the Royal Maternity and Women s Hospital, and the Association for the Relief of Incurables all Glasgow institutions —The late Mr John Sloughgrove of Lurleigh has bequeathed £150 to the Essex County Hospital £200 each to the Royal London Ophthalmic Hospital and the Reedham Asylum for Fatherless Children, £300 to Dr Barnardo s Homes and £250 each to the London Hospital and the Eastern Counties Asylum for Idiots —The late Miss Isabella Mary Peploe Smith of Onslow square S W , bequeathed £500 each to the Cancer Hospital Brompton the Consumption Hospital Brompton and the Society for the Prevention of Cruelty to Animals

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION OF HISTORY OF MEDICINE

Casanova's Memoires

A MEETING of this section was held on Dec 20th, 1916 Dr NORMAN MOORE, ex President being in the chair

Dr J D ROLLESTON read a paper on the Medical Interest of Casanova's Mémoires He said that as a child Casanova appeared to have suffered from adenoids and small pox His sanguine temperament predisposed him to epistaxis to which he was subject from childhood and to piles which he first developed during one of his imprisonments From early adult life onwards he had attacks of fever possibly malarial in origin, and at the age of 45 he had a severe attack of lobar pneumonia He had numerous attacks of venereal disease—gonorrhœa and soft chancre and possibly syphilis, as might have been expected from his own account of his life He apparently sought medical advice on each occasion, and no sequelæ resulted In old age he suffered from gout and his death was probably due to septic absorption, secondary to enlargement of the prostate Originally intended for the medical profession, Casanova retained throughout his life his interest in medicine as is shown by his descriptions of disease his criticism of doctors his dogmatic opinions on medical subjects his successful simulation of various maladies and his incursions into the field of therapeutics

Reviews and Notices of Books.

Diseases of the Umbilicus

By THOMAS S CULLEN, M B , Associate Professor of Gynæcology, Johns Hopkins University With 269 illustrations London and Philadelphia W B Saunders Company 1916 Pp 665 Price 35s net

THIS volume contains a complete account of the various diseases affecting the umbilicus and the urachus Not only has Dr Cullen collected all that is known about these conditions but he has also carefully recorded the more important cases, so that his work will be invaluable for reference to any future workers and serve as a foundation on which they may build

It would seem hardly possible that so many pages could be needed to describe the diseases of so small an area of the body as the umbilicus This book however deals not only very fully with all the known diseases of the navel but also with such other matters as the omphalomesenteric duct and vessels Meckel s diverticulum and the urachus The importance of the embryology of the umbilicus is very considerable because so many of the lesions are due to a partial or complete lack of closure of the omphalomesenteric duct or of the urachus The section devoted to this subject is extremely clear and is illustrated by a very fine series of drawings by Max Brödel The many interesting and instructive points which a detailed study of the anatomy reveals are well set out in Chapter II and the four plates showing the different forms of the umbilicus will be a revelation to those who have never studied this region particularly Umbilical infections and hæmorrhage in the new born child happily have lost the importance they once had but an account of many of the old epidemics is given by the author and their relation to infections of the umbilical stump clearly shown A large number of cases of the curious tumours formed by remnants of the omphalomesenteric duct the so-called umbilical polyp are collected and given in full while the chapters dealing with a patent omphalomesenteric duct and prolapse of the bowel through such a duct are most interesting As the author rightly points out when a small umbilical polyp is noticed after the cord has come away the probable persistence of other portions of the omphalomesenteric duct such as a Meckel s diverticulum or a cord from the mesentery to the umbilicus may be remembered and the added possibility of intestinal obstruction developing later in life explained to the parents It is interesting to find that most of the cases of so-called dermoids of the umbilicus turn out on further investigation to be nothing more than inflammation due to the irritation of an umbilical concretion the presence of caseous material and wool from the patient's clothing having led to an erroneous diagnosis in many of the cases Records of cases of Paget's disease, diphtheria and syphilis of the umbilicus are given, and also numerous cases illustrative of the escape of intra and extra abdominal fluid mostly pus, through the umbilicus as well as cases of umbilical fistulæ

Among the most curious of all the conditions described is the series collected by Dr Cullen of umbilical tumours containing uterine mucosa or remnants of Müller's ducts, in reality adenomyomata of the umbilicus It was a case of carcinoma of the umbilicus which first led the author to a study of the whole subject, and the chapter on that condition contains the records of many cases of both primary and secondary carcinoma of this region These clinical histories show that the development of a small, hard umbilical nodule in a patient at or beyond middle age should at once raise suspicion as to the presence of some intra abdominal malignant growth, and if there be symptoms suggestive of carcinoma of the stomach or gall bladder the probability will become almost a certainty Urachal anomalies, such as cysts, large and small simple and infected, patency of the urachus and urinary fistulæ may give rise to a great deal of inconvenience and present clinical features often difficult of diagnosis. They are all, however, very fully described by the author, and a reference to this work should assist in clearing up many diagnostic puzzles of this nature.

The whole is a monument of industry and skill, and will form the most complete and important work on this subject for many years to come

---

Tratado de Pediatria

Por el Dr MARTINEZ VARGAS Tomo I, Fundamentos de la Pediatria With 12 figures and 27 plates Barcelona J Vives Pp xiv -959

Dr Martinez Vargas, who is professor of pædiatry in the University of Barcelona, founder and President of the Spanish Pædiatric Society and member of many learned societies both Spanish and foreign is to be warmly congratulated on this first volume of what, if the standard here set is maintained in the two further volumes promised will be a really monumental contribution to the study of his subject, using the word in its widest and most comprehensive sense Dr Vargas connotes by pædiatry not merely the study of the diseases of children from the standpoints of pathology diagnosis and therapeutics but also a fairly detailed consideration of the anatomy physiology hygiene and vital statistics of infancy and childhood, he pays some attention to the history of pædiatry, its literature and its development in civilised countries throughout the world

In the first chapter, headed "General Considerations" (*Generalidades*) Dr Vargas defines pædiatry as that department of medicine which takes for its subjects of study infancy and childhood in such of their aspects and relations as are of special interest to the physician. He goes on to discuss the limits of the subject and some of the special characteristics of infancy and childhood their vulnerability to morbific influences on the one hand, their quick reaction and recovery on the other, the readiness with which anæmia comes on in any complaint tending to chronicity, the rapidity with which, in serious illnesses exhaustion both supervenes and is recovered from, the influence of growth and the preponderance of the lymphatic system. Next he deals with the anatomy of infancy and childhood when the thymus gland its anatomy and special *functions* are discussed fully Then, after describing the special physiology of the new born infant he passes to a detailed consideration of the subject of infant feeding This section is of especial value and is abreast of our present knowledge of the subject Sections on dentition and growth complete the consideration of the special physiology of children and the remainder of this section is devoted to digestion respiration and other functions common to the child and the adult For the rest the book deals systematically with the hygiene, pathology and therapeutics of childhood

The author's treatment of his subject is thorough and is characterised by a lucidity and sureness of touch which are the obvious fruit of wide knowledge and practical experience. The publisher is to be congratulated on the excellence of the plates and figures illustrating the work.

LIBRARY TABLE

Infection and Immunity A Text book of Immunology and Serology for Students and Practitioners By CHARLES E SIMON, B A, M D, Professor of Clinical Pathology at the College of Physicians and Surgeons, &c, Baltimore. Third edition, revised and enlarged Illustrated London Baillière, Tindall, and Cox. 1916 Pp 352 Price 14s net — Dr Simon's practical and clearly written book has been brought up to date and some new matter introduced Abderhalden's protective ferments receive sufficient notice and recent work on the Wassermann reaction has necessitated the re writing of this section Allusion is briefly made to more speculative work, such as the avoidance of anaphylactic shock by the production of anti anaphylaxis, and the recognition of protection against diphtheria toxin by an allergic reaction The treatment of the whole subject gains greatly in interest in this way Dr Simon primarily conceived his book for the enlightenment of the general practitioner In its present form he believes that it may serve as a basis for a course of systematic instruction, and in this we agree with him

The Charaka Club Vol IV New York William Wood and Co 1916 —The fourth volume of the proceedings of the Charaka Club has much the same character as that of its predecessors, to which we have already made reference in these columns The members of the club number some of the most prominent medical men who are practising or who have practised their profession in the United States, its object is to read papers and to promote discussion upon medico historical subjects There is no doubt that the interest of medical men in literary and artistic matters bearing on medicine has steadily increased of late, and to this agreeable fact it is quite likely that the publications of the Charaka Club have contributed, for the first two volumes are now out of print and their messages must have been widely disseminated though the membership of the club is small The most important article in the present volume is a learned and fully illustrated dissertation upon Saint Cosmo and Saint Damien, the patron saints of surgeons apothecaries, and barbers, whose presentations confront us so frequently in the picture galleries of Venice and Florence Other interesting papers are one by Dr Collins on the literary leanings of the physicians of the eighteenth century and one entitled "The Development of Anatomical Illustrations of the Nervous System," by Dr C L Dana Vesalius stands out among all the early illustrators of neurology for his knowledge and accuracy but the diagrams made practically at the same time—i e 1545—by Charles Estienne (Stephanus) are wonderfully good judging by the examples furnished by Dr Dana. A sad history attaches to a sketch of the history of the University of Alexandria as the author Dr J G Mumford died just before its publication A biographical note on Antonio Scarpa is supplied by Dr A G Gerster Dr Pearce Bailey sends a short story of some medico psychological interest and the Bacon and Shakespeare controversy is reviewed from the botanical aspect by Dr G L Walton

The Care of the School Child Edited by JAMES KERR M A. M D Cantab London The National League for Physical Education and Improvement *1916 Pp 230* Price 2s 6d —Bishop Boyd Carpenter introduces the reader to an admirable series of popular monographs, each by an expert, reprinted from lectures delivered under the auspices of the National League for Physical Education and Improvement during the summer months of 1916 The lectures are popular in the best sense, they may readily be understood by anyone who cares to read them with attention but they contain the most recent knowledge on the subject in hand and the proper deductions *from* this knowledge The chapters on malnutrition and the cripple child seem to us specially helpful. The book will be read with advantage by parents teachers nurses, health visitors, medical students, and even practitioners

Human Temperaments By CHARLES MERCIER, M D Lond, F R C P Lond *London* The Scientific Press, Limited Pp 91 Price 1s net —Dr Mercier in this small book sets out the description of ten well known types of character drawn from his personal study of men and women He begins by amusing and adroit chapters defining temperament generally cleverness and capability, and proceeds to describe the artistic religious, envious, jealous, and *suspicious* temperaments the man of action the practical man, the man of fads, the man of business, and the philosopher The essays are written in Dr Mercier's well known style—they are witty, pithy, and dogmatic, and display a wide range of observation and learning Thinking people must endorse a great many of Dr Mercier's generalisations—a statement which is likely to tempt Dr Mercier to modify them, but no one who presumes to have opinions of his own, and who possesses any experience with which to back them, is likely to agree completely with him, so that opportunities for battle are provided We recommend the brochure cordially to our readers It is always extremely readable and often very wise

Wheels An Anthology of Verse Oxford B H Blackwell Pp 84 Price 2*s* 6*d* net —We are not often asked to express an opinion upon verse and, when we are, the object of the writer has generally been the illustration by social incidents or pathological phenomena of some medical doctrine or moral Such volumes are almost invariably failures, dull when they are serious and unspeakably so when they are in jocose vein "Wheels" has no medical aspects whatever, save the unconscious revelation by the authors that the psychology of the cultivated youth of to day finds ready and graceful expression in verse—where their fathers wrote short stories and their grandfathers long essays, they sing The camps and the trenches during the past two years have produced many copies of verses having claim to notice as beautiful poetry, and "Wheels," though little of its contents may have been written in the circumstances of war, has an origin similar to that of the rapidly increasing war anthology It is composed, speaking for its common and essential quality, of impressions suddenly seized and handed on by writers who are conscious of what has been suggested to themselves and who are determined to share the suggestion with others The idea of these young poets is that the rôle of poetry is rather to crystallise fleeting views and aspects, to catch and fix vague and half formed ideas, than to do any of the brave things associated in popular literature with the title of poet—to lead to uplift, to amaze The inspiration of these nine different writers—different in style, technique, and standard of accomplishment—has been a common one They strive to show that any impression received by one person should be communicable to others by the medium of symbolic word pictures, and says the preface,

> Our words are turned to spokes that thoughts may roll
> And form a jingling chain around the world
> (Itself a fabulous wheel controlled by Time
> Over the slow incline of centuries)

We recommend the book to lovers of verse, leaving them to decide which spoke of the wheel they prefer, and to guess which individual singer is most likely in the future to gain a large audience or make a stronger individual effort. The contributors are Edith, Osbert and Sacheverell Sitwell, E Wyndham Tennant, Arnold James, Victor Perowne Nancy Cunard, Helen Rootham and Iris Tree

Poland's Case for Independence A Series of Essays illustrating the Continuance of Her National Life London George Allen and Unwin, Limited Pp 352 Price 7*s* 6*d* net —The essays which make up this book have been supplied by the Polish National Committee and have been written to prove that the national life of Poland has never ceased to exist despite the brutal fate which has been meted out to the country by the militarism of more powerful States The book interprets the manifestation of that life to foreigners and especially to the people of Great Britain, who have been persistently friendly to the Poles and in our opinion the claim of the writers is made entirely good that a country which has manifested such indestructible vitality has a right to the independence she claims The essays comprise one by Dr R W Seaton Watson on the landmarks of Polish history and another by Mr Rajmund Kucharski describing the persistent struggle for independence Mr Arthur F Gurney contributes usefully on the population question showing what were the extensive territories which up to 1772 constituted the Commonwealth of Poland and what were the nationalities of the various inhabitants This chapter appropriately precedes an essay by Mr Stanislaw Posner upon Poland as an independent economic unit and the book closes with sketches of the history of intellectual Poland its literature art and music. From the outset of the war it has been felt that the settlement of Poland will form a question of the utmost importance and one whose adjustment requires a sympathetic knowledge of Polish affairs such as is here shown

JOURNALS

Annals of Tropical Medicine and Parasitology, Vol. X, No 1.—This number of the annals contains four articles three of which are contributed by Dr J W Scott Macfie, of the West African Medical Staff and pathologist to the colony of the Gold Coast, the fourth being furnished by Professor J W W Stephens, of the University of Liverpool Dr Scott Macfie's first paper describes a fourth variety of trichonocardiasis affecting the shafts of the hairs in the axilla and groin, and caused by *Nocardia tenuis*, either alone or associated with a chromogenic organism His second contribution is entitled "Observations on Urinary Amœbiasis," and in this he makes reference to three cases which were recently investigated in the Gold Coast the infection in these instances, as well as in the few others already reported by previous observers being due to *Entamœba histolytica* Urinary amœbiasis, it appears, may be due to a primary infection, or it may be secondary to amœbic dysentery Cystitis, tumour of the bladder and gonorrhœa are said to be predisposing causes Dr Scott Macfie's third contribution deals with the morphology of certain spirochætes of man and other animals and is illustrated by a number of drawings in the text He describes a spirochæte which was found in the discharge from a mild case of vaginitis in a native woman, this organism being regarded as the causal agent of the disease Another spirochæte was discovered inhabiting the bladder of a male patient suffering from chronic cystitis, while a third variety of spirochæte was found in the throat of a native affected by pharyngitis Included in this paper are some interesting observations on the intestinal spirochætes of certain of the lower animals, including the monkey, rat sheep, cattle, goat and pig, in the fæces of which spirochætes of the *S eurygyrata* type were discovered Professor Stephens's paper is a continuation of his previous "Studies in Blackwater Fever," and in it he urges the importance of population statistics being supplied in connexion with reported cases of this disease He points out that it is high time that the disputed questions regarding this malady were settled and that systematic attempts should be made to obtain detailed information from official and other sources in localities affected by blackwater fever The incompleteness of the statements sent by some observers often rendered their contributions entirely valueless For the assistance and guidance of those who may in future compile local statistics of this disease, Professor Stephens puts forward several forms which can be filled up giving all the information that is needed

British Journal of Ophthalmology —The appearance of the first number of this journal the title page of which is the epitaph of the Royal London Ophthalmic Hospital Reports, the *Ophthalmic Review*, and the *Ophthalmoscope* marks the beginning of a new era in the literature of British ophthalmology The journal is in the enviable position of being without a rival, a position which is not free from danger Judging, however by the first number and by the imposing list of names of the editorial committee, which includes ophthalmologists of all parts of the Empire there would seem to be little fear of the journal succumbing from lack of driving power The editor Mr Sydney Stephenson, founded the *Ophthalmoscope* and by his zeal and skill made it a great success His long experience is a most valuable asset, and he is ably seconded by the assistant editor of the *Ophthalmic Review* Mr Erskine Henderson After a few remarks on the origin of the journal and the expression of a cordial welcome by American colleagues the Nestor of English ophthalmology Mr Priestley Smith leads off with a highly scientific communication on the Blood Pressure in the Eye and its Relation to the Chamber Pressure We consider it a good omen that original research is thus early and emphatically recognised and that the second place should be given to pathology in a paper on Choroidal Melanomata by Mr Foster Moore Then follow three papers on the removal of foreign bodies by the magnet the most important of which by Mr M H Whiting and Mr C Goulden, records the experiences and lessons of war work in France In the abstracts from ophthalmic literature the excellent method of collecting several papers on allied subjects for review is adopted Book notices and notes on matters of current interest conclude the number Of the 74 pages 42 are devoted to original communications The paper printing and numerous illustrations are all excellent We wish our new contemporary every success

A UNIQUE "EVERY CONTINGENCY" INSURANCE

The ideal insurance for professional men is one which covers (1) sickness of all kinds, (2) accidents of all kinds, (3) death, or survival to age 65 The Combined Policy of the Medical Sickness and Accident Society has been specially drawn up to provide for all of these contingencies—the rate charged is the lowest obtainable, the Society deals *only* with medical and dental practitioners, is mutual, and was established in 1884

EXAMPLE.

At age 30 an annual premium of £13 8s 6d will insure the following benefits—During incapacity from illness or accident, £3 3s per week for first 26 weeks and £1 11s. 6d. per week during remainder of illness to age 65 At age 65 or previous death, £300

Sickness and accident claims are paid every week by cheque, and death claims on production of satisfactory evidence Survival claims are paid on the 65th birthday

Practitioners should write the Secretary for full prospectus

GALYL

Framboesia
Sleeping Sickness

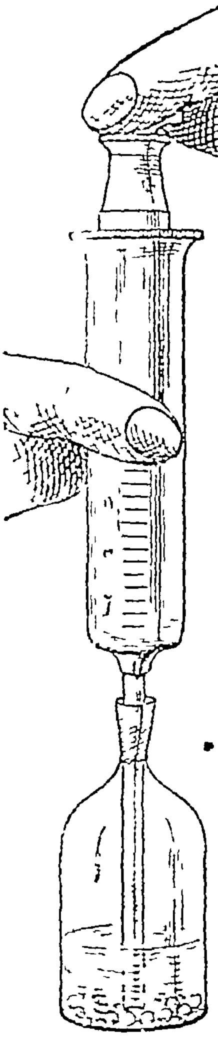

Fig 1

Practical work with GALYL in the shape of

60,000 **INTRAVENOUS** (Dilute and Concentrated) and **INTRAMUSCULAR INJECTIONS** administered in Military Naval, and the principal General Hospitals throughout the United Kingdom, has demonstrated that this preparation is **more rapid and less toxic** in action than any compound of the '606' group which accounts for the **consistently excellent clinical results without any undesirable by-effects**

The other advantages of GALYL are

1 Distilled water only necessary for making the solution

2 GALYL can be injected in the dilute or concentrated form—**intravenously** —or in oily emulsion —**intramuscularly**

3 GALYL is a true Anti syphilitic, as shown by the results of the Wassermann test but contains a smaller percentage of Arsenic than any of the compounds of the "606" group

Forms:

For Intravenous Injections — (Fig 1)

(1) **DILUTE.** — GALYL is supplied in neutral glass ampoules containing the necessary dose of Sodium Carbonate, sterile distilled water only being used for the dissolution

(2) **CONCENTRATED** — A special outfit containing one dose GALYL, one ampoule sterilised solution and one small filter is supplied

Doses

0·10—0 15—0 20—0 25—0·30—0 35—0 40

(3) For Intramuscular Injections —

GALYL is supplied in **OILY EMULSION**

Preventive Treatment in Relation to Venereal Disease

IN every infectious complaint there is a stage between infection and the appearance of evidence of disease, that symptomless incubation period which is still full of mystery in spite of our increasing knowledge of the life history of disease germs This period should logically be the most favourable time for treating disease or—if exception be taken to the word treatment in this connexion—for the *preventive treatment* of disease, reserving the word *prevention* for the avoidance of infection Regarding the incubation period, then, as an ideal time for the application of measures of preventive treatment, the field of such treatment becomes a vast one if we only are aware in every case when infection actually takes place In most instances, however, exposure to infection passes entirely unnoticed, or if noticed the chances of escape are so great, and the risk from disease itself so small, as to lead most people to neglect treatment even if available Only in the case of dangerous and awe inspiring plagues, such as small pox and tetanus, is the demand for preventive treatment on the part of those who have been exposed to infection an urgent one, and it is well known how successful is the immediate vaccination or revaccination of small pox contacts and the preventive inoculation with tetanus antitoxin of the victims of grievous wounds

There is, however, a special case for preventive treatment The possibility of infection with venereal disease must be present to the minds of all, excepting the most carelessly ignorant, of those who indulge in promiscuous sexual intercourse A definite occasion for infection has been present which cannot be overlooked, and Sir BRYAN DONKIN S letter to the *Times* last week calls attention to the fact that it would be a fresh safeguard to the community as well as to the individual to antedate the treatment for venereal disease to the period of incubation, before the symptoms have had time to appear Scientific research has, he says, shown conclusively that venereal infection can be prevented more surely than it can be cured by even the best methods of prompt treatment, and this fact was securely established by the precise experiments of the late Professor METCHNIKOFF Sir BRYAN DONKIN S allusion is to the method of inunction of a calomel ointment as soon as possible after exposure to infection, described by METCHNIKOFF in his Harben lectures delivered in London ten years ago and translated from the French in our columns at the time How far progress has been made since then is witnessed by the fact that in military administration, directed to the only organised group of society in which, before the awakening of to day, measures had been adopted to deal with venereal diseases, this inunction has already become a routine measure An Army Order issued in March of last year directed medical officers to arrange an organised system by which soldiers who had exposed themselves to the danger of venereal infection were required to attend for treatment within 24 hours of infection Men returning to barracks at any hour of the day or night were to have access to a room in the charge of an orderly who should superintend an efficient urethral irrigation with permanganate solution and an inunction into the glans penis of calomel ointment (calomel 33 parts, lanolin 100, vaseline 10) We understand that in the case of one battalion of 1700 men in which these facilities for preventive treatment were introduced the incidence of venereal disease immediately fell to less than a quarter of its previous figure

The value of early preventive treatment, then, in the case of venereal disease is as well established as it is for small pox and tetanus, and its wide application is equally indicated in the interests of individual and public health Early preventive treatment must take its natural place in any well considered scheme for control of venereal disease It may well be that provision for the use of civilians of the facilities already provided for soldiers would result in a similar limitation of disease, and thus of the necessity for prolonged treatment We are only concerned now to consider in any detail the medical aspect of the question, believing, as we do, that here as elsewhere physical and moral hygiene go hand in hand, and that it is impossible to develop one at the expense of the other It has now come to be generally accepted that the provision of early and effective treatment of the diseases acquired by promiscuous sexual intercourse is not going to increase the incidence owing to the removal of moral restraint, but the idea of a Mikado deity who must not be thwarted in his schemes for making the punishment fit the crime has died very reluctantly The same mediæval doctrine has been applied during the lifetime of most of us to the treatment of the later stages and of the sequelæ of syphilis and gonorrhœa Not only did some of our medical charities refuse, with the countenance of the regulations under which they were founded, to assist the victims of venereal disease, as far as they were able to diagnose such victims, but even the medical schemes organised by the public for mutual medical benefit—medical aid associations and sick clubs—withheld treatment from venereal sufferers We have changed all that, and to day the municipal schemes for the control of venereal diseases concern themselves keenly with the treatment of the earlier stages of those diseases The application of the same doctrine to early preventive treatment is a logical step forward, and ought to be taken at once

---

Mobilisation of the Medical Profession

THE subject of the mobilisation of the medical profession came before a special meeting of the Panel Committee for the County of London on

Tuesday last, when a report submitted by the Finance and General Purposes Subcommittee was considered in detail The report recognised the urgent necessity of providing additional officers for the Royal Army Medical Corps, its authors being convinced by confidential information which had been submitted to them that a large number of additional practitioners would be required for military service

The very important resolution recently passed by the Central Medical War Committee with regard to mobilisation approved, it may be recollected, of the principle of mobilisation of the medical profession apart from any question of general mobilisation of the community For the Central Medical War Committee desire that every individual whose name is on the Medical Register shall be held bound to give such service as he is competent to give when required to do so by the State On this broad question of the mobilisation of the medical profession as an individual entity the Panel Committee for the County of London have made no pronouncement, but they consider that if such a proposal were carried into effect it is essential that the arrangements for mobilisation should be under the control of a purely professional committee They find that the Central Medical War Committee, strengthened in certain directions, would be the most suitable body to undertake the important work The recommendations of the Panel Committee provide accordingly for the addition to the Central Medical War Committee of "at least six practitioners actively engaged in panel practice, one of whom should be a woman," and they consider, further, that without serious interference with the medical needs of the civilian population much greater use could be made in the future of the part time services of civilian doctors Civilian doctors could, they hold, be advantageously employed in the treatment of sick and wounded soldiers whilst in hospitals, as well as for the discharge of other military duties at home We are certain that the members of the Panel Committee for the County of London are well aware of the difficulties attached to this proposal, but it is the expression of a very general feeling, and one which we share ourselves We believe that in this way an economy of personnel could be effected and more medical men found to meet the demands of the Director General of the Army Medical Service

We regret the recommendation of the Panel Committee that the members whom they desire to see added to the Central Medical War Committee should necessarily be engaged in panel practice The probability, of course, is that those selected for the purpose would be in active panel practice, but it is perilous to attach conditions which might become hampering The views of those in panel practice can be fairly stated by anyone really familiar with the circumstances and it is conceivable that panel practitioners might by restricting their representation to one of themselves be deprived of the offices of a particularly good nominee

Annotations.

"Ne quid nimis."

HEALTH OF THE PRISON POPULATION

FEW people regard the prison as a health resort, but the contention that such is the case in prisons in this country would be made plausible by a perusal of the report of the Commissioners of Prisons which we publish in another column The average death rate in local prisons for the last 25 years has been less than 0·5 per 1000 receptions, and although for the year under review it is nearly 50 per cent greater, the increase is entirely explainable by the altered age groups of the prison population Prisoners of military age naturally are healthier and contribute less to the prison death rate than do the older malefactors, and the actual number of prisoners of military age received in prisons has diminished to less than one third in the last three years and entirely out of proportion to the reduction in older prisoners The death rate from natural causes in convict prisons is, of course, much higher 6 per 1000 of the daily average population during the last ten years and 8 per 1000 for the year under review No emphasis can here be laid on slight fluctuations as the total convict population is so small—under 2000, in fact, at the end of the year No epidemic of infectious disease occurred during the year, and only 13 scattered cases in all, 3 each of enteric fever and erysipelas, the remainder being ordinary infectious fevers of a mild type A comparative picture of prison life under less healthy conditions may be gained from Lieutenant Colonel W J Buchanan's report for 1915 on the jails of the Bengal Presidency which has just come into our hands, and the comparison is not an unfair one in respect of numbers as the daily average number of prisoners is not widely different 11,311 under the care of the English Commissioners, and 14,494 in Bengal, bearing in mind however, that of the first number only about one fifth are convicts, while of the Bengalese 97 per cent are convicts There is the initial striking fact that the death rate amongst the Bengal convicts during 1915 was over 20 per 1000 being nearly three times the rate among convicts in the prisons of England and Wales Of the 264 deaths among Bengal convicts in 1915, 77 were due to dysentery 24 to malaria 18 to diarrhœa, in addition to 38 from tuberculosis and 26 from pneumonia Lieutenant-Colonel Buchanan, whilst attributing this melancholy death rate largely to the very serious overcrowding in the prisons, remarks that in the district jail of Barisal the persistent care and attention given by the medical officers has resulted in practically stamping out dysentery from this jail, but he goes on to record the very serious mortality in Dinajpur which blots the year's administration In this jail of 315 inmates there is a daily average sickness of 29 and a death rate of 119 per 1000, 18 deaths during the year being due to dysentery, 2 to malaria 4 to pneumonia and 2 to diarrhœa. In regard to this jail Lieutenant Colonel Buchanan writes "I have urgently pressed on Government the great need of a hospital here– This jail is one of the worst of the East Bengal jails, and the medical officer has not a fair chance in treating the sick drawn from an unhealthy district in the present old barrack wards used as a hospital

The standard of mental health of the prison population is not a high one for a variety of reasons The English Prison Commissioners report the number of persons in local prisons found to be insane after reception as 103 (126) and in convict prisons 36 (26), the numbers in brackets being those for the previous year Of the cases certified in local prisons three fourths were regarded as already insane on reception and another 7 showed symptoms of insanity within a month of reception The war has had a remarkable effect upon the prison mental standard on account of the absence, already noted, from the prisons of strong able bodied men The Commissioners record their belief that the country's call for men has appealed as strongly to the criminal as to other classes, and it is a remarkable fact that receptions to prison are now principally confined to the mentally as well as physically weak The Commissioners express their regret at the paralysing influence which the deficiency of State accommodation has exerted on the treatment of criminal defectives, but they look forward to the cessation of hostilities rendering possible an efficient administration of the Mental Deficiency Act The present method of dealing with the confirmed and hopeless inebriate also comes up again for censure

THE PIG AS A FOOD MIDDLEMAN

The Local Government Board and the Board of Agriculture and Fisheries are concerning themselves with the necessity for increasing the food productions of the country by the development of pig, poultry and rabbit breeding In regard to the two latter, few hygienic or dietetic problems arise But the recommendation to increase the number of pigs, and that not only in rural districts, where space is abundant and neighbours are distant, raises very different questions The hygienic aspect is at once apparent, and has led to the existence in a number of urban districts, as well as in a few rural ones, of by laws prohibiting the keeping of pigs within a prescribed distance of dwelling houses We learn, however, from a recent circular of the Local Government Board that a regulation is about to be made enabling any local authority to give permission for the keeping of pigs either generally or in particular cases, notwithstanding by laws to the contrary To those acquainted with the habits of the pig under favourable surroundings this relaxation will not appear unreasonable The pigsty often smells not because of the pig, but because of the ignorance of his keeper Provided with a small area for the purpose the pig will dispose of his excreta without any nuisance whatever and with incidental enrichment of the soil, while his sty remains cleanly It is the wholly confined pig who stinks But on the dietetic side, in recommending pig culture as an economical pastime the fact must not be lost sight of that the alimentary canal of the pig is adapted for much the same kind of food as the human child s The pig has no highly developed cæcum to deal with the conversion of cellulose into digestible carbohydrates The growing pig is a typical omnivore and ordinarily receives a large amount of nutritive material, some of which the growing child could well digest Experiments have shown that via the pig as middleman only some 25 per cent of the protein and some 45 per cent of the total energy value of the food supplied him is ultimately returned to the consumer as pork or bacon Brokerage of at least 55 per cent, which may well be largely exceeded, is charged by the pig Pig culture can afford no excuse for wasteful housekeeping, and the presence in the pig bucket of food which the family could have consumed is a disgrace to any patriotic housekeeper The inspection of the amount of household waste might well become part of the sanitary inspector's routine duties at the present time The case for pig keeping is more cogent where food refuse from hotels and institutions is in question Food waste is apparently inseparable from civilised town life, and the pig may well be employed to redeem some of this waste if proper care is given to his lodging

THE INTERNAL FORM OF HODGKIN'S DISEASE

In the *Journal of the Royal Army Medical Corps* Lieutenant T H Whittington has reported a case of the "internal" form of Hodgkin s disease of acute onset with relapsing pyrexia and signs and symptoms chiefly abdominal, which was very difficult of diagnosis and deceived the "very elect" A private aged 19 years, was admitted to a base hospital from the trenches in Flanders on Nov 21st, 1915 He looked pale and complained of pains in the soles, but nothing abnormal was seen in the feet On the 24th the abdomen was distended, slightly tender all over, and rather rigid The temperature ranged from 103° to 104° F, the tongue was dry and brown A leucocyte count showed a leucopenia of 3500 On the 27th he was sent to a hospital for infectious diseases as probably a case of enteric fever, and came under Lieutenant Whittington s care He was very pale, with a rather 'renal" appearance, and complained of headache There was occasional muttering delirium with picking at the bedclothes The pulse was very soft and occasionally dicrotic There was marked tenderness with dullness on percussion in the left hypochondrium and left lumbar regions This dullness appeared to be splenic, reaching down four finger breadths below the umbilicus, but the spleen was not felt The stools were fluid and yellow No enlarged glands were felt The serum reactions for the typhoid and paratyphoid bacilli were negative The diagnoses so far suggested were acute peritonitis, recurrent appendicitis, and typhoid fever, the last being favoured During the next week the abdominal distension diminished, enabling a firm and slightly tender spleen to be felt The hæmoglobin was only 52 per cent From Dec 2nd to 5th the temperature fell and the patient rapidly improved On the 31st he again became listless and pale, and complained of pains in the soles and toes The temperature again rose and the spleen rapidly enlarged. The temperature soon fell, only to rise again on Jan 4th, 1916, when the spleen was still more enlarged and the liver slightly so Blood examination showed 3000 white and 3,600,000 red cells per c.mm A differential count gave polymorphonuclears 80 per cent, lymphocytes 15, and large mononuclears 5 Several consultants saw the patient, and the diagnoses suggested were a typhoid relapse, splenic anæmia, and tuberculous peritonitis, but Hodgkin s disease, Malta fever, kala azar, congenital syphilis, and septicæmia were also discussed He again improved, but another relapse followed, the abdomen being distended and showing free fluid in the flanks There appeared to be an indefinite mass above the umbilicus He became very emaciated and jaundiced, —

and died on Feb 15th, 12 weeks after the onset At the necropsy much yellowish fluid was found in the abdomen The spleen was thrice the normal size and hard and showed on its surface and on section yellowish white spots An enlarged gland in the portal fissure seemed to press on the hepatic duct The retroperitoneal glands formed a large, irregularly lobulated, hard mass Some enlarged glands were found below and behind the inner ends of the clavicles Microscopic examination showed the typical appearance of Hodgkin s disease In McNalty s study of "Lymphadenoma with Relapsing Pyrexia"[1] 8 cases out of 32 are described as without enlargement of the superficial glands In only 2 of these was the duration shorter than in the present case In a man, aged 23 years, the mediastinal glands, spleen, liver, and kidneys were affected and he died after five weeks In the other the mesenteric and bronchial glands, liver, and spleen were affected, and death occurred after seven weeks The other patients lived for periods varying from 4 to 15 months

THE PARLIAMENTARY REPRESENTATION OF DUBLIN UNIVERSITY

WE published last week a letter from the Professor of Anatomy and the Professor of the Practice of Medicine in Dublin University, urging upon those of our readers who are entitled to vote for the Parliamentary representation of the University to record their support at the forthcoming election in favour of Sir Robert Woods, M D Dub, who is standing as a non party candidate Sir Robert Woods approaches the electors with the plea that he is the representative of the medical faculty of the University, which is notoriously one of the most distinguished faculties, while Mr Arthur W Samuels belongs to the profession of law which, *except in one solitary instance*, has for half a century supplied the constituency with its Parliamentary member The issue, in fact is one to be decided between the profession of medicine and the profession of law, for both candidates disclaim party views in politics Mr Samuels describes himself as "a Unionist and Imperialist," with no reference to party interests Sir Robert Woods is equally detached In answer to a correspondent he has written "I shall resist with all my power any attempt to revive the Irish controversy during the period of the war and to coerce any section of the Irish people into a settlement which it does not desire If, however, with the full and free consent of the Unionists of Ulster and the Unionist minority of Dublin and the South of Ireland, and with the full sanction of the Imperial Parliament, a real settlement of the Irish question is evolved, after the war, by the united statesmanship of both countries I shall do my best to help it in every way We wish Sir Robert Woods every success, because it is constantly brought home to us that the presence of more medical men in the House of Commons would be of great value to the country The ignorance displayed by the majority of Members of Parliament upon all medical points is illustrated by the nature of the questions in the House of Commons no less than by the way in which medical, and indeed all scientific interests are too often sacrificed to the interests of other sections of the community At the Conference of Educational Associations held at the University of London last week Sir Alfred Keogh said it was a regrettable thing to find Cabinet Ministers prominent administrators, and other people in high positions having no knowledge whatever of the elementary facts of science He had to place scientific questions before these men and he found it difficult to get low enough to reach their level Every medical Member of Parliament helps to improve the situation, and from this point of view alone Sir Robert Woods may fairly expect votes

OSTEOCHONDROMATOSIS OF JOINT CAPSULES

IN 1900 Reichel published the first description of a rare condition characterised by the appearance of multiple osteochondromas in the capsules of one or more of the joints Dr J W Kopp[1] has recently recorded three new instances of this complaint affecting the knee joints in each patient, and he has found 11 others in medical literature In 10 of the total of 14 patients the knees were involved the ankle, wrist elbow, hip, and metacarpo phalangeal joint of the middle finger have also been found affected, each in different cases In three patients, including one of Dr Kopp's, both knee joints were diseased, otherwise the osteochrondromatosis has apparently been confined to a single articulation The disease may occur at any age, and although the new growths show no sign of malignancy they may recur after their operative removal, by arthrectomy or resection of the joint, has been attempted This, no doubt, is a consequence of incomplete removal In Reichel s case the patient was a man of 36 with a very chronic and almost painless affection of the knee The joint was opened and a quantity of blood was removed from its cavity, together with two handfuls of loose cartilaginous fragments Recovery followed, shortly afterwards Reichel opened the joint again and removed a number of loose, bluish white cartilaginous fragments, but an attempt to dissect out the whole capsule of the joint, which was beset with numerous cartilaginous nodules of various sizes, was baffled by the discovery of similar nodules on the cruciate ligaments Resection showed that the articular surfaces of the femur, tibia, and patella were unaffected and that the new growths originated in the capsule of the joint Dr Kopp s first patient was a healthy student, aged 24, who came under observation in 1911 with a history of slight pains in the right knee for four years The condition was attributed to trauma of an unusual character to which the attention of neurologists may be drawn—percussion of the patella with a percussor in a wanton moment during a joyous evening The patient s gait was normal, but there were symptoms of the nipping of a foreign body in the joint The joint itself showed an unsymmetrical swelling of the synovial membrane and the suprapatellar bursa, with fluctuation and limitation of movement to about 75° Numerous free foreign bodies could be felt in it and one, the size of a grape, lying on the inner side of the patella could be moved two inches in any direction but always returned to the same place, whence it was concluded that it had a peduncle All the other joints seemed normal This patient had had comparatively little trouble with his knee when he was seen again in 191-, and he refused operation Skiagrams were taken and are reproduced by Dr Kopp in his paper They show a curious dappling of most of the area subtended by the synovial membrane but no changes in the structure of the bone or their articular surfaces Dr Kopp s second patient a man of 39 gave a history of slight trauma of the knee some 15 years before Three years later he had had symptoms pointing to the nipping of a loose body in the joint Dr Kopp found swelling of the joint and suprapatellar bursa, and in both could be felt some movable and hard foreign bodies The joint was opened under ether anæsthesia, and an incomplete arthrectomy was performed Two free foreign bodies were found in the prepatellar bursa The outer surface of the synovial membrane was found to be studded with bluish white opalescent nodules, the largest as big as a pea There was no evidence of inflammation and the synovial fluid was clear Careful examination showed that these nodules arose from the synovial membrane only, and not from bone, cartilage, ligament, or muscle The ends of the bones exhibited the appearances of arthritis deformans in its early stages The patient made a good recovery from the operation and was well satisfied with its results when he was seen again 20 months later But a couple of foreign bodies could then be felt in the immediate vicinity of the right knee joint, and Dr Kopp concludes that it also was becoming affected with osteochondromatosis The third patient was an old woman of 77 with senile dementia, who had foreign bodies in both knee joints Operation was not contemplated, but Dr Kopp decided from the physical signs and skiagrams that he had here to do with a third case of this rare disease Discussing its general diagnosis, he says that it has to be distinguished from osteoarthritis localised in some diverticulum of the joint, from the intra articular exostosis cartilaginea first described by Volkmann in 1855, from arthritis deformans, and from the osteoarthropathies met with in tabes dorsalis and syringomyelia As another possible source of confusion he mentions the fabella, a sesamoid bone appearing not rarely in the external head of the gastrocnemius The pathogenesis of osteochondromatosis is uncertain Reichel attributed it to infection, Lexer (1907) refers it to a developmental defect in the differentiation of the mesenchyma of the joint, comparable to that resulting in the growth of enchondromas about the bones of the fingers and toes Dr Kopp agrees with Lexer The neoplasms removed from his second case were examined for him by Dr de Josselin de Jong, who states that in this instance the nodules began life as minute osteomas in the capsule of the joint, and ended up as foreign bodies free in the joint, where they became covered with connective tissue and cartilage, while their bony core might develop into a calcareous mass As for the treatment indicated, Dr Kopp believes that recurrence is likely to follow arthrectomy or excision of the capsule of the joint, and that nothing short of resection of the whole joint will give a permanent cure

SANITATION AND DISEASE IN BENGAL

THE work of combating disease in India is rendered difficult by the indifference of the people to elementary hygienic precautions The annual report for 1915 recently issued by the Sanitary Commissioner of Bengal illustrates this fact in a striking manner The ravages of cholera in the Presidency during the year were very great, the number of deaths due to that disease being over 130,000, an increase of 41,000 on the total of 1914 The districts which suffered most severely were Mymensingh and Malda, and the high rate recorded is explained by the action of the people themselves Dealing with Mymensingh, the civil surgeon writes ‘ In August, when a large part of the district was under water, dead bodies of cholera patients were, in two subdivisions of the district, thrown into the flood water, which spread the disease far and wide till the end of the year These two subdivisions were responsible for 18,819 deaths out of a total of 26 662 in the whole district This record is supplemented by the account given by the civil surgeon of what occurred in Malda “From some of the bordering villages dead bodies were thrown into the river, and this contaminated the water and facilitated the spread of the disease to the villages situated on it’ It is not surprising, in view of the facts we have cited, that the Sanitary Commissioner should declare that outbreaks of cholera must be counted as annual events so long as the majority of the sources of water supply remain subject to gross contamination But even where waterworks are installed and a pure supply is forthcoming the advantages thus afforded are not universally appreciated Thus, at Berhampore, which has been provided with a pipe supply, certain classes of the inhabitants persisted in drinking unfiltered water brought from the river, with the result that 74 deaths from cholera took place among them last year, while those who availed themselves of pipe water remained immune to the disease Bengal occupies the unhappy position of being the only part of India where the death rate exceeded the birth rate in 1915 The increase in mortality was largely due to cholera and small pox, while the diminution in the birth rate is ascribed to the deficiency in rainfall in 1914, which by preventing a decline in the prices of food grains affected the vitality of the poorer classes The Government resolution on the Sanitary Commissioner's report expresses the opinion that the best prospect of permanent improvement in village sanitation lies in the widespread formation of union committees and the free exercise of their powers of local taxation The Governor agrees with the Commissioner that much immediate improvement, which would also have an educative value, could be attained through the personal interest and initiative of district officials

---

THE death is announced, at the age of 90, of Jean Baptiste Auguste Chauveau, professor of comparative pathology in the Paris Natural History Museum, and one of the most famous physiologists of his time

---

A MEETING of the British Hospitals Association will be held at St Bartholomew's Hospital, London, on Friday Jan 26th, at 3 30 P M, when a paper will be read by Dr W J Howarth, medical officer of health for the City of London, on the Treatment and Control of Venereal Diseases, with Special Reference to the Voluntary Hospitals *At the close* of the proceedings the annual meeting of the association will be held to appoint officers for the ensuing year

---

THE Royal Institute of Public Health has arranged an admirable series of public lectures on health problems under war and after war conditions to be delivered every Wednesday afternoon at 4 P.M from Jan 17th to March 28th inclusive in the lecture room of the Institute at 37, Russell square Medical officers of health, medical practitioners, and all those engaged in public health and national services are invited to attend The first lecture, on Wednesday next, will be delivered by Dr Janet Lane Claypon on Child Welfare Work, with Sir Robert Morant in the chair Due notice of the other lectures will be given in the Diary

THE LANCET, VOL II, 1916
THE INDEX

THE Index and Title page to the volume of THE LANCET completed with the issue of Dec 30th will be ready on Jan 22nd Owing to the continued shortage in the paper supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W C, when a copy of the Index and Title page will be supplied free of charge

PRISON COMMISSIONERS' REPORT

THE report of the Commissioners of Prisons and the Directors of Convict Prisons for the year ended March 31st, 1916, which has been presented to Parliament, does not contain the usual report of the Medical Commissioners this report, along with those of the visiting chaplain and surveyor having been omitted on the recommendation of the Committee on Public Retrenchment A number of paragraphs in the report itself, however, deal with medical topics

Medical Matters Dealt with in the Report

The death rate in local prisons from natural causes was 0 77 per 1000 prisoners received, the average for the previous 25 years having been 0 49 per 1000 The death rate from natural causes in convict prisons was 8 2 per 1000 of the daily average population as compared with 6 1 for the past ten years But this apparent rise in death rate must be brought into relation with the great alteration in the age groups of the prison population An earlier paragraph explains the alteration thus —

> The enlistment of many habitual petty offenders of military age can be inferred from the fact that for the year ended March 31st, 1914, the percentage of male prisoners of the age categories over 40 received on conviction formed 40 per cent of the total population For the year ended March 31st, 1916, this percentage had risen to 49, while the actual number of prisoners received of military age had fallen from 61,739 to 19,169 during these years

The number of persons in local prisons found to be insane and certified as such after reception was 103, as compared with 126 last year and in convict prisons 36 as compared with 26 Of the 103 cases certified in local prisons 76 were found to be insane on reception and 7 exhibited symptoms of insanity within a month of reception Many of those who were in prison for some time before the usual symptoms of insanity were observed were known to be of weak intellect or mentally impaired on reception, or to have been previously insane As with the death rate so with the incidence of insanity, the figures do not reflect the normal results of prison life

The war has again had a marked effect on the average mental condition of the prison population, an effect which is described in the following interesting paragraph —

> One of the notable effects of the war on the prison population has been that the receptions are now for the most part confined to the physically and mentally weak The general standard of physique is now much inferior to that of prisoners admitted into prison in normal times, while the percentage of strong able bodied men is comparatively small There is every reason to believe that the country's call for men appealed as strongly to the criminal as to other classes and if it had been possible to place under scrutiny every case admitted into prison within military age there is little doubt but that the vast majority of cases would have been found to be physically unfit A young burglar one of a gang of five told the chaplain of a London prison that his four pals had enlisted, two had been killed and two others wounded He said he meant to go and " do his bit " as soon as he got out of prison—a promise which he faithfully observed

The number of prisoners who were released from local prisons on medical grounds exclusive of pregnancy &c but including 8 cases temporarily released under Section 17 (6) of the Criminal Justice Administration Act 1914 was 31 and from convict prisons 2. There were 4 suicides in local prisons during the year and none in convict prisons The daily average number of prisoners in hospital in local prisons was 361—225 males and 136 females—this being a proportion to the general prison population of 3 5 and 7 3 per cent respectively Thirteen cases of infectious disease were reported during the year—enteric fever, 3, erysipelas, 3, measles, 4, scarlet fever, 2, mumps, 1—as compared with 11 cases last year—viz., enteric fever, 1, chicken pox, 2, scarlet fever, 2, diphtheria 2, mumps, 1, and erysipelas, 3

Mental Deficiency Act —Convictions for Drunkenness

As in the last year's report allusion is again made to the difficulties which have arisen, owing to the outbreak of war and other causes in the exercise of the Mental Deficiency Act so far as it relates to inmates of penal institutions The Commissioners regard the record for the year under report as not an encouraging one During the year 204 prisoners—130 males and 74 females—were certified under Section 1 of the Mental Deficiency Act, as compared with 248 last year A large number of the 248 certified during 1914-15 have been received again many several times, on re conviction Orders were made by the Secretary of State, under Section 9 of the Act, in 39 cases—10 males and 29 females—and these were removed to certified institutions or in the case of some of the females, to the Farmfield State Institution In addition 26 males and 22 females were handed over to local authorities on discharge The absence of institutional accommodation for defectives, and particularly State accommodation for males, exercises, in the Commissioners' view a paralysing influence on operations under the Act as regards the disposal of criminal defectives But a more hopeful note is struck for the future

On the vexed question of the alleged increases of drunkenness among women much fresh light is thrown by an inquiry made by the Lady Inspector of Prisons into the character of the population committed for drunkenness to Holloway Prison

The inquiry showed that during the three years 1913, 1914, and 1915 10,888 committals on conviction of drunkenness were recorded against 1628 women, who, including the convictions incurred in years preceding 1913, had on their combined records a total of 30,936 convictions Of these 1628 individual prisoners—

1092 were received in	1913,	incurring that year	2768 convictions
1045	1914		3931
813	1915		4189

The average convictions, therefore per individual rose from 2 6 in the year 1913 to slightly over 5 in 1915 Amongst the 1628 women was selected a group of 25, who, at the end of 1915, had each received ten or more convictions for this offence All are stated to have been first offenders in 1913 or 1914 By the end of 1915 they had amassed a total of 353 convictions—viz , 69 in 1913 134 in 1914 and 150 in 1915 As regards first offenders in the drunkard class, the totals received in each year were 113, 113, and 37 respectively

The inquiry at Holloway thus substantiated the observations of several governors and chaplains at other prisons—viz , that a falling population is at the present time contributing more convictions per annum than was the case before the war If the average rate of convictions per annum incurred by each individual at Holloway Prison for the years 1913-14 and 1915-16 respectively be applied to the total receptions on convictions of drunkenness for the whole country a result is arrived at which shows an actual falling off of about two thirds in the numbers received for this offence

In connexion with this increased rate of convictions for drunkenness per individual the Commissioners comment on the curious fact that there should have been a great fall in the number of habitual drunkards committed to inebriate reformatories So far as the metropolis is concerned the numbers fell from 95 in 1913 to 9 in 1915 This is due in part to the war , but the failure of the Inebriates Act, 1898 to deal with the problem of habitual alcoholism must now in the Commissioners view, be admitted The Commissioners sum up the matter thus " If medical observation shows that mental causes enter into the history of the confirmed and hopeless inebriate, the Mental Deficiency Act now provides the opportunities for dealing otherwise with the repeated offence of drunkenness than by the useless and we might say senseless methods hitherto prevailing of repeated sentence to short terms of ordinary imprisonment This affords no cure—perhaps only an encouragement It is unscientific in principle, and further degrades the subject—man or woman

KING EDWARD'S HOSPITAL FUND FOR LONDON

A MEETING of the Governors and General Council of King Edward's Hospital Fund for London for the purpose of awarding grants to the hospitals, convalescent homes, and consumption sanatoria for 1916 was held on Dec 15th at St James s Palace, London

Lord IVEAGH, who presided, read a letter from the King congratulating the Council of the Fund on the distribution of £170 000 this year, £30 000 more than last year s total, and £12,500 over the previous record achieved in the years just before the war His Majesty also expressed the hope that the public would help to maintain this record.

Lord REVELSTOKE (the honorary treasurer) reported that the net receipts for the year to Dec. 11th apart from receipts on capital account had amounted to £269 526 18s 6d This included £100 000 cash received from Sir Walter Trower in respect of the residue of the estate of the late Isabella Countess of Wilton and the Fund had already had transferred to it securities amounting to over £22,000 The Finance Committee were retaining the cash uninvested so as not to hamper the discretion of the Council in deciding as to the use of the money in the event of any emergency

Sir WILLIAM COLLINS on behalf of the League of Mercy said there was hardly any reason to doubt that the League would be in a position to make for the fourth year in succession a grant of at least £14 000 to the King Edward s Hospital Fund and also to make a distribution of something like £3000 in the extra metropolitan district

Sir WILLIAM CHURCH (the chairman of the Distribution Committee) presented a report which stated that the sum available for distribution amongst the London hospitals was £162 500 as against £133 500 in 1915 This was the largest sum that has ever been distributed by the Fund amongst the hospitals, being an increase of £29 000 over the last two years, and £11,500 over the previous maximum of £151,000 which was reached in the years immediately preceding the war The increase in grants in aid of maintenance was £28 075 and became possible because of the postponement of building schemes and the reduction of grants towards capital expenditure Of the capital grants of £19 075 recommended this year only £6525 was on account of schemes begun since the outbreak of war on the ground of exceptional urgency, the balance had been devoted to relieving hospitals of capital liabilities incurred before the war They had as far as possible distributed the increased grants in proportion to the probable urgency of need in 1916 and had given rather greater weight than usual to the more permanent elements which affected a hospital's power to stand increased financial strain, such as the relative amount of fixed income and the relative amount of available reserve funds, but the actual results of 1916 could not be taken into account until the next distribution The number of hospitals applying for grants was 107 being three in excess of last year The committee Sir William Church continued received yearly evidence of the increasing work done by the voluntary hospitals in the cure or prevention of disease in coöperation with State or municipal authorities, apart from the treatment of naval and military patients This was one of the numerous ways in which the hospitals took their part in promoting public health. The latest development in this direction was the preparation by various hospitals of schemes for the treatment of venereal diseases in coöperation with the Local Government Board and the London County Council in accordance with the recommendations of the recent Royal Commission. In one case, that of the London Lock Hospital an application for a capital grant in aid of sanitary and other improvements at the female hospital had been received and in view of the importance of increasing the efficiency of this hospital in these respects the committee recommended a substantial grant towards the sanitary improvements The committee further recommended that the Council which had already by large grants enabled the Male Lock Hospital to be brought thoroughly up to date, should also offer substantial assistance towards an approved scheme for the reconstruction of the Female Lock Hospital

Mr F M FRY then presented the list of awards which has already been published in the press The largest individual grant, £15,000, has been given to the London Hospital, while Guy s Hospital follows with £9000 The smallest grants (£25) go to some of the cottage hospitals

Dr EDWIN FRESHFIELD (the chairman of the Convalescent Homes Committee) presented a report stating that the sum available for distribution amongst convalescent homes and consumption sanatoria was £7500, as against £6500 in 1915 the largest sum that had ever been placed at the disposal of the Convalescent Homes Committee. The number of applications eligible for consideration amounted to 42 from convalescent homes and 9 from consumption sanatoria, as against 41 and 9 respectively last year The committee had made a slight increase this year in the number of beds reserved at consumption sanatoria for the use of patients in London hospitals owing to the fact that certain women's beds no longer available had been replaced by children's beds The accommodation thus secured amounted to 53 beds at six sanatoria

The list of grants recommended by the Convalescent Homes Committee having been presented by Mr J G GRIFFITHS,

Lord IVEAGH, in moving the adoption of the report and awards said it was with great satisfaction that they found themselves able to make a record distribution, and this apart from supplementary grants rendered possible by the generosity of Sir Ernest Cassel It was one of the functions of the Fund to serve as a steadying influence on the finances of the hospitals The amount which the hospitals would get from the Fund in grants to maintenance, even in this record year, was only a little more than one ninth of the total ordinary expenditure, while the very large increase in the maintenance grants would not cover the increase in their ordinary expenditure since the war began, reckoning only the year 1915 There was no doubt moreover that the need of the hospitals would continue to grow in the near future The burden of 1916 would inevitably be greater and if the Fund was to continue to do its part an increased distribution might become desirable He wished to express the indebtedness of the Fund for the legacies of £20 000 received, under the will of the late Lady Brownlow, on the death of Sir Charles Brownlow, and £10 000 very kindly allocated to the Fund by the executors of the late Thomas Stephen Whitaker in the exercise of their discretionary power

The Duke of NORFOLK having seconded the motion, the adoption of the reports was carried unanimously

A meeting of the General Council of King Edward's Hospital Fund for London was held on Monday afternoon Jan 8th, at the offices of the Fund, 7, Walbrook, E C There were present the Speaker of the House of Commons (the Right Hon James W Lowther, M P), in the chair, the Earl of Bessborough, the Viscount Knutsford, Lord Burnham, Lord Somerlayton (honorary secretary), the President of the Royal College of Physicians (Dr Frederick Taylor), the Right Hon C Stuart-Wortley K C, M P, Sir William S Church, Bart, Sir Owen Philipps, M.P, Sir Horace Marshall, Mr Frederick M Fry (honorary secretary), Mr John G Griffiths (honorary secretary), Mr Robert Fleming, Dr Edwin Freshfield, Mr W J H. Whittall The appointments were announced of Mr W J H Whittall to the General Council and of Sir Edward Hope, K.C B, to the Executive Committee The resolutions providing for the work of the Fund for 1917, which were approved at the meeting of the Governors and General Council, were formally adopted

MEDICINE AND THE LAW

Humphreys v Miller, Rendell, and Harbord

IN this case as will be remembered, it was shown that a lodging house keeper let rooms to Mr H O Miller, who resided there with his daughter until his death from leprosy, being attended in his last illness by Mr E A Harbord The plaintiff afterwards brought an action tried by Mr Justice Darling with a special jury, claiming damages against the executor of the deceased his daughter, and Mr Harbord, on the ground that there was an implied warranty when the rooms were taken that Mr Miller was not suffering from any disease which would make it unfit or dangerous for him to occupy them or would prevent them from being in future let as furnished rooms, that Miss Miller knew that her father was not a fit person to occupy the rooms, and that the father the daughter, and Mr Harbord concealed the fact from the plaintiff in consequence of which the rooms were let After a great deal of evidence had been given the jury returned answers in the plaintiff s favour to all the questions put to them finding as facts that Mr Miller when he took the rooms was liable to infect persons and furniture with leprosy, and that he and his daughter knew it, that the disease was communicable by infection or contagion in England, that Miss Miller and Mr Harbord fraudulently misrepresented Mr Miller as fit to occupy the rooms, that they concealed from the plaintiff that Mr Miller was suffering from a disease which made him unfit and dangerous to occupy the rooms, that Mr Harbord acting as agent for the other two, stated that Mr Miller was not suffering from any contagious or infectious disease, and that this was untrue, as he and Miss Miller knew, that all three conspired to conceal the state of Mr Miller from the plaintiff, and made false statements with that object Damages to the extent of £250 were awarded. Counsel for Mr Harbord asked for judgment for his client *non obstante veredicto*, on the ground that there was no obligation upon him to disclose his patient's condition to the plaintiff and no evidence that he did not believe that in this country leprosy was neither infectious nor contagious After further argument to the effect that there was no evidence to support the jury s findings, Mr Justice Darling gave judgment for the defendants

The Court of Appeal has since affirmed the decision of Mr Justice Darling Lord Justice Swinfen Eady held that there is no foundation in law for the argument that there is a warranty or condition that when a person takes furnished rooms he shall not be suffering from any disease which may be infectious or contagious, that there was no evidence that Miss Miller knew that her father was suffering from leprosy or from any infectious or contagious disease With regard to Mr Harbord the evidence showed that he had nothing to do with the original taking of the rooms, he had told the landlady when questioned by her, that the deceased was not suffering from an infectious disease, but had warned her to be careful and that no one else was to use the lavatory used by the patient According to the evidence, the risk of infection with leprosy in this country was practically *nil* and that was Mr Harbord s view He honestly expressed the opinion that he held, and was under no obligation to divulge to the lodging house keeper anything with regard to his patient Moreover, the plaintiff could have determined the tenancy by giving a week s notice to her tenants His lordship held that in view of the above Mr Justice Darling was right in holding that there was no evidence upon which to base any finding which involved either of the defendants in liability to the plaintiff Lord Justice Bankes in concurring, said 'I see no evidence whatever on which it can be suggested as against this medical man that he did not honestly believe that speaking practically, there was no danger either of infection or contagion from this particular disease The appeal was therefore dismissed That this case should have ended as it did, and that Mr Justice Darling s judgment should have been upheld is eminently satisfactory and the medical profession as well as Mr Harbord is to be congratulated upon the result arrived at The charge made in claiming damages was a charge of deliberate falsehood and conspiracy involving known danger to the health of innocent people for the convenience and in the interest of the medical man s patient It is established that of all this there was no evidence The fact that a case of leprosy was involved with the exposition of medical opinion as to this disease added incidental interest to the trial

Coroners Juries in War Time

Three sane and useful suggestions have been made by Mr S Ingleby Oddie in a letter to the *Times* for economising money and men s time in connexion with inquests He recommends that the coroner should be enabled by an Act of Parliament (1) to hold inquests without a jury, or (2) to hold them with a jury of seven or (3) to order post mortem examinations before deciding that an inquest is to be held Of these it will probably be agreed by many that the adoption of numbers (1) and (3) not alternatively but simultaneously would be a useful innovation and if such adoption were to be for the period of the war only would constitute an experiment which need not be continued if it should prove unsuccessful The third suggestion deals with a recommendation often made by coroners which found [illegible] support at the hands of the Departmental Committee on Coroner Law in 1910 The first should be favourably considered by those who remember that many coroners are, and all might be, medical men with sufficient legal training for the performance of a coroner s duties so far as they entail knowledge of law It may be pointed out that the economy of money, time, and man power effected would be on a more important scale than that involved in the recent abolition of reports of certifying surgeons on accidents which had a similar object in view Also it would not involve injustice to anyone whose functions would be dispensed with, or any loss of protection to the persons on whose behalf they are now exercised

The Slingsby Case

In this case a declaration was claimed under the Legitimacy Declaration Act 1858 with regard to the alleged child of Commander C H R Slingsby It will be remembered that Mr Justice Bargrave Deane found that the child was borne by Mrs Slingsby at San Francisco, the allegation on the other side being that he had been procured for her from another woman The Court of Appeal held that the evidence did not justify the finding of Mr Justice Bargrave Deane, and the appeal on behalf of the child to the House of Lords has now been dismissed A curious feature of the case consisted in the calling in of Sir George Frampton, the well known sculptor to express an opinion upon the question of physical resemblance on the part of the child to the parents who claimed him as theirs Sir George Frampton was of the opinion that a strong likeness existed, and the judge appears to have thought so too As to this Lord Loreburn, in the House of Lords, expressed the opinion that Mr Justice Bargrave Deane s views of the evidence must have unconsciously been influenced by Sir George Frampton, while Lord Sumner said that any weight that might be attached to likeness was overborne by other evidence

PUBLIC HEALTH OF MANCHESTER

IN his recently published annual report Dr James Niven gives an instructive account of the health of the city of Manchester in the year 1915 and of the various preventive measures carried out under his direction, special reference being made to the administrative action taken locally for the control of tuberculosis The appearance of this volume shortly after the issue of Dr W H Hamer s report[1] for the same period affords opportunity for comparing the statistical records and sanitary defences of a well equipped provincial city with corresponding data for the metropolis

The recorded death rate" of Manchester was equal to 16 31 per 1000 at all ages or 1 42 below the decennial average rate The tabular records submitted are less complete than previously and there is great doubt as to the total population of the city Owing to the large number of enlistments the age constitution of the civil population has seriously changed Nor is this change confined to the male sex, since recent alterations of occupation have affected the distribution of women also Either for reasons of economy in war time or else because of uncertainty attaching to population estimates many of the usual tables are omitted in this report But this omission has to some extent been compensated for by the Registrar General who publishes detailed periodical returns of mortality and of disease notification in each of the great British towns[2]

The national records deal with the entire areas of the several towns but in the present report essential particulars are given for each of the statistical divisions of the city From these we learn that as compared with the decennial average, the crude death rate in 1915 shows a marked improvement in North Manchester and a considerable improvement in South Manchester but a falling off in the old Manchester township This supports the conclusion previously reached that the poorer classes have suffered disproportionally in the last two years Nevertheless the average position of the Manchester working classes is believed to have improved and there has been less pauperism in 1915 than in the two preceding years In order to avoid the uncertainty attaching to estimates of population, the actual deaths (in place of the death-rates) from the chief causes in the last three years are summarised in an instructive table. The most striking feature in this table is the great increase in the deaths from tuberculous phthisis and from heart disease in 1915 as compared with the year preceding the war. This abrupt rise, especially in the case of the first-named disease, may be due in part to the strain induced by war conditions and in part to the lack of new dwellings for the growing population. Balancing the gains and losses of life during 1915 in comparison with those in the previous ten years, the largest gains are found to be under the heads of pneumonia, whooping-cough, nervous disease, and diarrhoea. The losses are greatest under the heads of cancer, heart disease, and old age.

[1] THE LANCET [illegible] ii 37

[2] THE LANCET 1 [illegible] ii 1

Infant mortality.—Inasmuch as the mortality in the first year after birth is based, not on the numbers estimated to be living at that age, but on the number of infants born alive during the year, it is obviously unaffected by uncertainties as to population. It is also independent of the birth-rate. In the year under notice infant mortality in Manchester was at the rate of 129 per 1000 births, as compared with 112 in London, 117 in the 96 great towns, and 110 in England and Wales.[1] Infant mortality in the first three months of life was lower than in any previous year. It was also low in the second three months, but in the last half of the first year it was comparatively high. Compared with the preceding three years we learn that during the first three months after birth proportionally fewer deaths occurred in 1915 from convulsions, premature birth, atrophy, and suffocation—i.e., from that class of disease which it is our main object to prevent. In the second three months the result is less favourable. During the last half of the first year of life there were in 1915 relatively fewer deaths from whooping-cough, tuberculosis, and convulsions, but relatively more from measles, diphtheria, lung disease, and violence, the excess under lung disease being probably determined by measles prevalence.

Administrative Control of Pulmonary Tuberculosis.

Towards the close of last century a national movement was initiated for the suppression of tuberculosis. In a recent classical work entitled "A Campaign against Consumption,"[2] by the late Dr. Arthur Ransome, then professor of public health in the Victoria University, the history of this movement was traced to its local origin half a century ago. The author asserts that the honour of being the first authority to suggest and eventually to adopt measures for the suppression of this scourge may fairly be claimed by Manchester. Dr. Ransome's own entrance into the campaign dates back to the year 185[illegible] and to the establishment in Manchester and Salford of a weekly return of common diseases, prominent among which was phthisis. There is good reason to believe that these returns, voluntarily contributed by about 30 medical residents for more than 12 consecutive years, were not merely the forerunners but powerful incentives to the more complete notification returns which are now everywhere required under statute law. In 1884 a large area of old and dilapidated dwellings in Ancoats was officially condemned as unfit for human habitation. This area was computed to afford shelter for 5500 persons of the poorest class, who on a five years' average were succumbing to phthisis at the rate of 5·3 per 1000 living. The buildings on this area, and other insanitary areas in the older parts of the city, have recently been demolished by the municipality, and better house accommodation has been provided for the displaced occupants.

Notification and treatment of phthisis.—Dr. Niven will be recognised by his medical colleagues generally as one of the earliest among advocates of the compulsory notification of phthisis, as well as of its preventive treatment, as a matter of State policy. He is to be congratulated on the large measure of success he has achieved in Manchester in dealing with the administrative difficulties of the crusade—difficulties which were at one time regarded as insurmountable by many of his contemporaries. Systematic notification of phthisis is still on its trial in Manchester, London, and some other towns, and as local experience accumulates the results should materially influence administrative action. In the present report there appears a standard table showing the number of primary notifications during the year. This table is identical in form with that contained in Dr. Hamer's London report, and we may presume that the respective health officers will avail themselves of this and similar methods for the comparison of future results. The usual table showing the facts and rates of notification in the several districts has been prepared for 1915, but is not inserted in this report. The notification rate exceeds the death-rate in various degrees. The case of Withington is especially notable. In this residential district the deaths steadily outnumber the reported cases, pointing to a failure in the duty of notification. The earliest records available respecting the results of notification are those for 1899—since which year more than 28 000 phthisical patients have been visited by the staff. In 25 000 cases sputum has been examined, with positive results in one-third of the cases. Not fewer than 27 105 of the patients have been isolated in hospital and the houses disinfected after removal of the patients.

The loss of life from phthisis in 1915 was in excess of the average. It was 1·76 per 1000 living of both sexes at all ages, and was above the mean rate in the preceding ten years by 0·09 per 1000. It was also above the rate in the County of London by 0·16 per 1000. When the total deaths in a single year are distributed over several age-groups in both sexes the rate of mortality for each separate group cannot usefully be compared with corresponding rates for previous years. Nevertheless the numbers of deaths at each age may properly be compared, and thus an approximate idea of the course of events may be presented. By this means we learn that *among males* the phthisis deaths were more numerous in 1915 than in any of the preceding ten years. (This statement relates exclusively to the civil population, which includes Manchester soldiers discharged on account of phthisis.) The most marked increase occurs at ages 15–19, 20–24, and 35–44, but not at ages 25–34, nor at ages under 15. *Among females* also there is a corresponding excess in the deaths, the increase being nearly as great as among males. The greatest increase occurs at ages 25–34. It is possible that the additional stress of work now thrown on both sexes and the increased demand for workers in the prime of life may account for the great addition to the death toll. When the deaths from bronchitis are examined similarly they present parallel rises to those from phthisis, both among males and females. Pneumonia shows no such increase; on the contrary, among males the deaths thus returned in 1915 were fewer than in any of the preceding ten years. Among females they were fewer than in any of the ten except 1905.

Milk and tuberculosis.—The milk supply of Manchester is derived from about 69 farms, chiefly in the counties of Cheshire, Derbyshire, Staffordshire, and Lancashire. During the year 91 samples of milk were examined, and in a useful table the percentages are given of farmers in each county whose milk was found to cause tuberculosis. It is noteworthy that none of the farmers in Derbyshire or in Staffordshire sent tuberculous milk to the city. In Dr. Niven's report for 1913 particulars were given of the successful manner in which the work of keeping a herd of cows free from tuberculosis is being carried on. The milk produced by this herd is still supplied to the large fever hospital at Monsall and to the sanatorium at Baguley.

Poverty in relation to phthisis.—A most instructive table is inserted giving a classification of the cases whose family income fell short of a standard rate according to the ascertained "shortage," and showing the institutional assistance obtained for these patients. The standard was based on that given by Mr. B. Rowntree in his book on poverty. The table indicates under several headings the numbers living and the numbers dead at the end of 1915, the numbers admitted to the several hospitals, and the number receiving institutional assistance. It would appear from this table that in 1915 phthisis was more fatal to the poorer classes of cases than in previous years.

Report of the Tuberculosis Officer.

A valuable report by Dr. D. P. Sutherland is appended to that of the medical officer of health. It contains minute details of the manifold operations of his department in the course of the year. We can only briefly refer to the analysis of cases in which the results of institutional and dispensary treatment are shown. In the "residential" that the father the daughter, and Mr Harbord concealed the fact from the plaintiff in consequence of which the rooms were let After a great deal of evidence had been given the jury returned answers in the plaintiff's favour to all the questions put to them finding as facts that Mr Miller when he took the rooms was liable to infect persons and furniture with leprosy, and that he and his daughter knew it, that the disease was communicable by infection or contagion in England, that Miss Miller and Mr Harbord fraudulently misrepresented Mr Miller as fit to occupy the rooms, that they concealed from the plaintiff that Mr Miller was suffering from a disease which made him unfit and dangerous to occupy the rooms, that Mr Harbord acting as agent for the other two, stated that Mr Miller was not suffering from any contagious or infectious disease, and that this was untrue, as he and Miss Miller knew, that all three conspired to conceal the state of Mr Miller from the plaintiff, and made false statements with that object Damages to the extent of £250 were awarded. Counsel for Mr Harbord asked for judgment for his client *non obstante veredicto*, on the ground that there was no obligation upon him to disclose his patient's condition to the plaintiff and no evidence that he did not believe that in this country leprosy was neither infectious nor contagious After further argument to the effect that there was no evidence to support the jury's findings, Mr Justice Darling gave judgment for the defendants

[2] Published in [illegible] by the Cambridge University Press. Pp. [illegible] Price 1s. 6d.

The Court of Appeal has since affirmed the decision of Mr Justice Darling Lord Justice Swinfen Eady held that there is no foundation in law for the argument that there is a warranty or condition that when a person takes furnished rooms he shall not be suffering from any disease which may be infectious or contagious that there was no evidence that Miss Miller knew that her father was suffering from leprosy or from any infectious or contagious disease With regard to Mr Harbord the evidence showed that he had nothing to do with the original taking of the rooms, he had told the landlady when questioned by her, that the deceased was not suffering from an infectious disease, but had warned her to be careful and that no one else was to use the lavatory used by the patient According to the evidence the risk of infection with leprosy in this country was practically *nil* and that was Mr Harbord's view He honestly expressed the opinion that he held, and was under no obligation to divulge to the lodging house keeper anything with regard to his patient Moreover, the plaintiff could have determined the tenancy by giving a week's notice to her tenants His lordship held that in view of the above Mr Justice Darling was right in holding that there was no evidence upon which to base any finding which involved either of the defendants in liability to the plaintiff Lord Justice Bankes in concurring, said 'I see no evidence whatever on which it can be suggested as against this medical man that he did not honestly believe that speaking practically, there was no danger either of infection or contagion from this particular disease The appeal was therefore dismissed That this case should have ended as it did, and that Mr Justice Darling's judgment should have been upheld is eminently satisfactory and the medical profession as well as Mr Harbord is to be congratulated upon the result arrived at. The charge made in claiming damages was a charge of deliberate falsehood and conspiracy involving known danger to the health of innocent people for the convenience and in the interest of the medical man's patient It is established that of all this there was no evidence The fact that a case of leprosy was involved with the exposition of medical opinion as to this disease added incidental interest to the trial

Coroners' Juries in War Time

Three sane and useful suggestions have been made by Mr S Ingleby Oddie in a letter to the *Times* for economising money and men's time in connexion with inquests He recommends that the coroner should be enabled by an Act of Parliament (1) to hold inquests without a jury, or (2) to hold them with a jury of seven or (3) to order post mortem examinations before deciding that an inquest is to be held Of these it will probably be agreed by many that the adoption of numbers (1) and (3) not alternatively but simultaneously would be a useful innovation and if such adoption were to be for the period of the war only would constitute an experiment which need not be continued if it should prove unsuccessful The third suggestion deals with a recommendation of one made by coroners which found strong support at the hands of the Departmental Committee on Coroners Law in 1910 The first should be favourably considered by those who remember that many coroners are, and all might be medical men with sufficient legal training for the performance of a coroner's duties so far as they entail knowledge of law It may be pointed out that the economy of money time, and man power effected would be on a more important scale than that involved in the recent abolition of reports of certifying surgeons on accidents which had a similar object in view Also it would not involve injustice to anyone whose functions would be dispensed with, or any loss of protection to the persons on whose behalf they are now exercised

The Slingsby Case

In this case a declaration was claimed under the Legitimacy Declaration Act 1858 with regard to the alleged child of Commander C H R Slingsby It will be remembered that Mr Justice Bargrave Deane found that the child was borne by Mrs Slingsby at San Francisco the allegation on the other side being that he had been procured for her from another woman The Court of Appeal held that the evidence did not justify the finding of Mr Justice Bargrave Deane and the appeal on behalf of the child to the House of Lords has now been dismissed A curious feature of the case consisted in the calling in of Sir George Frampton, the well known sculptor, to express an opinion upon the question of physical resemblance on the part of the child to the parents who claimed him as theirs Sir George Frampton was of the opinion that a strong likeness existed and the judge appears to have thought so too As to this Lord Loreburn, in the House of Lords, expressed the opinion that Mr Justice Bargrave Deane's views of the evidence must have unconsciously been influenced by Sir George Frampton, while Lord Sumner said that any weight that might be attached to likeness was overborne by other evidence

PUBLIC HEALTH OF MANCHESTER

Report of the Tuberculosis Officer

A valuable report by Dr D P Sutherland is appended to that of the medical officer of health It contains minute details of the manifold operations of his department in the course of the year We can only briefly refer to the analysis of cases in which the results of institutional and dispensary treatment are shown In the "residential

that the father, the daughter, and Mr Harbord concealed the fact from the plaintiff in consequence of which the rooms were let. After a great deal of evidence had been given the jury returned answers in the plaintiff's favour to all the questions put to them, finding as facts that Mr Miller when he took the rooms was liable to infect persons and furniture with leprosy, and that he and his daughter knew it, that the disease was communicable by infection or contagion in England, that Miss Miller and Mr Harbord fraudulently misrepresented Mr Miller as fit to occupy the rooms, that they concealed from the plaintiff that Mr Miller was suffering from a disease which made him unfit and dangerous to occupy the rooms, that Mr Harbord, acting as agent for the other two, stated that Mr Miller was not suffering from any contagious or infectious disease, and that this was untrue, as he and Miss Miller knew, that all three conspired to conceal the state of Mr Miller from the plaintiff and made false statements with that object. Damages to the extent of £250 were awarded. Counsel for Mr Harbord asked for judgment for his client *non obstante veredicto*, on the ground that there was no obligation upon him to disclose his patient's condition to the plaintiff and no evidence that he did not believe that in this country leprosy was neither infectious nor contagious. After further argument to the effect that there was no evidence to support the jury's findings, Mr Justice Darling gave judgment for the defendants.

---

[3] See table on p [illegible] of Registrar-General's return for the fourth quarter of [illegible]

[4] Published in 1915 by the Cambridge University Press Pp 253 Price 10s 6d.

The Court of Appeal has since affirmed the decision of Mr Justice Darling. Lord Justice Swinfen Eady held that there is no foundation in law for the argument that there is a warranty or condition that when a person takes furnished rooms he shall not be suffering from any disease which may be infectious or contagious, that there was no evidence that Miss Miller knew that her father was suffering from leprosy or from any infectious or contagious disease. With regard to Mr Harbord the evidence showed that he had nothing to do with the original taking of the rooms, he had told the landlady, when questioned by her, that the deceased was not suffering from an infectious disease, but had warned her to be careful and that no one else was to use the lavatory used by the patient. According to the evidence, the risk of infection with leprosy in this country was practically *nil* and that was Mr Harbord's view. He honestly expressed the opinion that he held and was under no obligation to divulge to the lodging house keeper anything with regard to his patient. Moreover, the plaintiff could have determined the tenancy by giving a week's notice to her tenants. His lordship held that in view of the above Mr Justice Darling was right in holding that there was no evidence upon which to base any finding which involved either of the defendants in liability to the plaintiff. Lord Justice Bankes, in concurring, said "I see no evidence whatever on which it can be suggested as against this medical man that he did not honestly believe that, speaking practically, there was no danger either of infection or contagion from this particular disease." The appeal was therefore dismissed. That this case should have ended as it did, and that Mr Justice Darling's judgment should have been upheld is eminently satisfactory, and the medical profession as well as Mr Harbord is to be congratulated upon the result arrived at. The charge made in claiming damages was a charge of deliberate falsehood and conspiracy involving known danger to the health of innocent people for the convenience and in the interest of the medical man's patient. It is established that of all this there was no evidence. The fact that a case of leprosy was involved with the exposition of medical opinion as to this disease added incidental interest to the trial.

Coroners' Juries in War Time

Three [illegible] and useful suggestions have been made by Mr S Ingleby Oddie in a letter to the *Times* for economising money and men's time in connexion with inquests. He recommends that the coroner should be enabled by an Act of Parliament (1) to hold inquests without a jury or (2) to hold them with a jury of seven or (3) to order post mortem examinations before deciding that an inquest is to be held. Of these it will probably be agreed by many that the adoption of numbers (1) and (3) not alternatively but simultaneously would be a useful innovation, and if such adoption were to be [illegible] to the period of the war only would constitute an experiment which need not be continued if it should prove unsuccessful. The third suggestion deals with a recommendation often made by coroners which found strong support at the hands of the Departmental Committee on Coroners Law in 1910. The first should be favourably considered by those who remember that many coroners are and all might be medical men with sufficient legal training for the performance of a coroner's duties so far as they entail knowledge of law. It may be pointed out that the economy of money, time, and man power effected would be on a more important scale than that involved in the recent abolition of reports of certifying surgeons on accidents which had a similar object in view. Also it would not involve injustice to anyone whose functions would be dispensed with, or any loss of protection to the persons on whose behalf they are now exercised.

The Slingsby Case

In this case a declaration was claimed under the Legitimacy Declaration Act, 1858, with regard to the alleged child of Commander C H R Slingsby. It will be remembered that Mr Justice Bargrave Deane found that the child was borne by Mrs Slingsby at San Francisco, the allegation on the other side being that he had been procured for her from another woman. The Court of Appeal held that the evidence did not justify the finding of Mr Justice Bargrave Deane, and the appeal on behalf of the child to the House of Lords has now been dismissed. A curious feature of the case consisted in the calling in of Sir George Frampton, the well known sculptor, to express an opinion upon the question of physical resemblance on the part of the child to the parents who claimed him as theirs. Sir George Frampton was of the opinion that a strong likeness existed, and the judge appears to have thought so too. As to this Lord Loreburn, in the House of Lords, expressed the opinion that Mr Justice Bargrave Deane's views of the evidence must have unconsciously been influenced by Sir George Frampton, while Lord Sumner said that any weight that might be attached to likeness was overborne by other evidence.

PUBLIC HEALTH OF MANCHESTER

IN his recently published annual report Dr James Niven gives an instructive account of the health of the city of Manchester in the year 1915 and of the various preventive measures carried out under his direction, special reference being made to the administrative action taken locally for the control of tuberculosis. The appearance of this volume shortly after the issue of Dr W H Hamer's report[1] for the same period affords opportunity for comparing the statistical records and sanitary defences of a well equipped provincial city with corresponding data for the metropolis.

The "recorded death rate" of Manchester was equal to 16·31 per 1000 at all ages, or 1·42 below the decennial average rate. The tabular records submitted are less complete than previously and there is great doubt as to the total population of the city. Owing to the large number of enlistments, the age constitution of the civil population has seriously changed. Nor is this change confined to the male sex, since recent alterations of occupation have affected the distribution of women also. Either for reasons of economy in war time or else because of uncertainty attaching to population estimates many of the usual tables are omitted in this report. But this omission has to some extent been compensated for by the Registrar General, who publishes detailed periodical returns of mortality and of disease notification in each of the great British towns.[2]

The national records deal with the entire areas of the several towns, but in the present report essential particulars are given for each of the statistical divisions of the city. From these we learn that as compared with the decennial average the crude death rate in 1915 shows a marked improvement in North Manchester and a considerable improvement in South Manchester, but a falling off in the old Manchester township. This supports the conclusion previously reached that the poorer classes have suffered disproportionally in the last two years. Nevertheless the average position of the Manchester working classes is believed to have improved, and there has been less pauperism in 1915 than in the two preceding years. In order to avoid the uncertainty attaching to estimates of population the actual deaths (in place of the death rates) from the chief causes in the last three years are summarised in an instructive table The most striking feature in this table is the great increase in the deaths from tuberculous phthisis and from heart disease in 1915 as compared with the year preceding the war This abrupt rise, especially in the case of the first named disease, may be due in part to the strain induced by war conditions and in part to the lack of new dwellings for the growing population. Balancing the gains and losses of life during 1915 in comparison with those in the previous ten years, the largest gains are found to be under the heads of pneumonia, whooping cough nervous disease, and diarrhoea. The losses are greatest under the heads of cancer, heart disease, and old age

[2] THE LANCET, [illegible]

Infantile mortality—Inasmuch as the mortality in the first year after birth is based, not on the numbers estimated to be living at that age but on the number of infants born alive during the year, it is obviously unaffected by uncertainties as to population It is also independent of the birth rate In the year under notice infant mortality in Manchester was at the rate of 129 per 1000 births as compared with 112 in London, 117 in the 96 great towns and 110 in England and Wales[3] Infant mortality in the first three months of life was lower than in any previous years It was also low in the second three months, but in the last half of the first year it was comparatively high. Compared with the preceding three years, we learn that during the first three months after birth proportionally fewer deaths occurred in 1915 from convulsions premature birth atrophy and suffocation—i.e from that class of disease which it is our main object to prevent. In the second three months the relation is less favourable. During the last half of the first year of life there were in 1915 relatively fewer deaths from whooping-cough tuberculosis and convulsions but relatively more from measles diphtheria, lung disease and violence, the excess under lung disease being probably determined by measles prevalence

Administrative Control of Pulmonary Tuberculosis

Towards the close of last century a national movement was initiated for the suppression of tuberculosis In a recent classical work[4] entitled "A Campaign against Consumption" by the late Dr Arthur Ransome, then professor of public health in the Victoria University the history of that movement was traced to its local origin half a century ago The author asserts that the honour of being the first authority to suggest and eventually to adopt measures for the suppression of this scourge may fairly be claimed by Manchester Dr Ransome's own entrance into the campaign dates back to the year 1860, and to the establishment in Manchester and Salford of a weekly return of common diseases, prominent among which was phthisis There is good reason to believe that these returns voluntarily contributed by about 30 medical residents for more than 12 consecutive years were not merely the forerunners but powerful incentives to the more complete notification returns which are now everywhere required under statute law In 1834 a large area of old and dilapidated dwellings in Ancoats was officially condemned as unfit for human habitation. This area was supposed to afford shelter for 5500 persons of the poorest class who on a five years average were succumbing to phthisis at the rate of 5 3 per 1000 living The buildings on this area, and other insanitary areas in the older parts of the city have recently been demolished by the municipality and better house accommodation has been provided for the displaced occupants

Notification of tuberculous phthisis—Dr Niven will be recognised by his medical colleagues generally as one of the earliest among advocates of the compulsory notification of phthisis as well as of its preventive treatment as a matter of State policy He is to be congratulated on the large measure of success he has achieved in Manchester in dealing with the administrative difficulties of the crusade—difficulties which were at one time regarded as insurmountable by many of his contemporaries Systematic notification of phthisis is still on its trial in Manchester London and some other towns and as local experience accumulates the results should materially influence administrative action In the present report there appears a standard table showing the number of primary notifications during the year This table is identical in form with that contained in Dr Hamer's London report, and we may presume that the respective health officers will avail themselves of this and similar methods for the comparison of future results The usual table showing the facts and rates of notification in the several districts has been prepared for 1915, but is not inserted in this report The *notification rate* exceeds the *death rate* in various degrees The case of Withington is especially notable In this residential district the deaths steadily outnumber the reported cases, pointing to a failure in the duty of notification The earliest records available respecting the results of notification are those for 1899—since which year more than 28 000 phthisical patients have been visited by the staff In 25 000 cases sputum has been examined with positive results in one-third of the cases Not fewer than 27 106 of the patients have been isolated in hospital and the houses disinfected after removal of the patients

The loss of life from phthisis in 1915 was in excess of the average It was 1 76 per 1000 living of both sexes at all ages, and was above the mean rate in the preceding ten years by 0·09 per 1000 It was also above the rate in the County of London by 0 16 per 1000 When the total deaths in a single year are distributed over several age groups in both sexes the *rate of mortality* for each separate group cannot usefully be compared with corresponding rates for previous years Nevertheless the *number of deaths* at each age may properly be compared, and thus an approximate idea of the course of events may be presented. By this means we learn that *among males* the phthisis deaths were more numerous in 1915 than in any of the preceding ten years (This statement relates exclusively to the civil population, which includes Manchester soldiers discharged on account of phthisis) The most marked increase occurs at ages 15–19 20–24 and 35–74 but not at ages 25–34 nor at ages under 15 *Among females* also there is a corresponding excess in the deaths the increase being nearly as great as among males The greatest increase occurs at ages 25–34 It is possible that the additional stress of work now thrown on both sexes and the inordinate demand for workers in the prime of life may account for the great addition to the death toll When the deaths from bronchitis are examined similarly, they present parallel rises to those from phthisis both among males and females Pneumonia shows no such increase, on the contrary among males the deaths thus returned in 1915 were fewer than in any of the preceding ten years Among females they were fewer than in any of the ten except 1906

Milk and tuberculosis—The milk supply of Manchester is derived from about 69 farms chiefly in the counties of Cheshire Derbyshire Staffordshire, and Lancashire. During the year 91 samples of milk were examined and in a useful table the percentages are given of farmers in each county whose milk was found to cause tuberculosis. It is noteworthy that none of the farmers in Derbyshire or in Staffordshire sent tuberculous milk to the city In Dr Niven's report for 1913 particulars were given of the successful manner in which the work of keeping a herd of cows free from tuberculosis is being carried on The milk produced by this herd is still supplied to the large fever hospital at Monsall and to the sanatorium at Baguley

Poverty in relation to phthisis—A most instructive table is inserted giving a classification of the cases whose family income fell short of a standard rate according to the ascertained "shortage" and showing the institutional assistance obtained for these patients The standard was based on that given by Mr B Rowntree in his book on poverty The table indicates under several headings the numbers living and the numbers dead at the end of 1915 the numbers admitted to the several hospitals and the number receiving institutional assistance. It would appear from this table that in 1915 phthisis was more fatal to the poorer classes of cases than in previous years

Report of the Tuberculosis Officer

A valuable report by Dr D P Sutherland is appended to that of the medical officer of health. It contains minute details of the manifold operations of his department in the course of the year We can only briefly refer to the analysis of cases in which the results of institutional and dispensary treatment are shown In the "residential

Poverty in relation to phthisis—A most instructive table is inserted giving a classification of the cases whose family income fell short of a standard rate according to the ascertained shortage" and showing the institutional assistance obtained for these patients The standard was based on that given by Mr B Rowntree in his book on poverty The table indicates under several headings the numbers living and the numbers dead at the end of 1915 the numbers admitted to the several hospitals and the number receiving institutional assistance. It would appear from this table that in 1915 phthisis was more fatal to the poorer classes of cases than in previous years

Report of the Tuberculosis Officer

A valuable report by Dr D P Sutherland is appended to that of the medical officer of health. It contains minute details of the manifold operations of his department in the course of the year We can only briefly refer to the analysis of cases in which the results of institutional and dispensary treatment are shown In the 'residential that the father, the daughter, and Mr Harbord concealed the fact from the plaintiff in consequence of which the rooms were let After a great deal of evidence had been given the jury returned answers in the plaintiff s favour to all the questions put to them finding as facts that Mr Miller when he took the rooms was liable to infect persons and furniture with leprosy, and that he and his daughter knew it , that the disease was communicable by infection or contagion in England , that Miss Miller and Mr Harbord fraudulently misrepresented Mr Miller as fit to occupy the rooms , that they concealed from the plaintiff that Mr Miller was suffering from a disease which made him unfit and dangerous to occupy the rooms , that Mr Harbord, acting as agent for the other two, stated that Mr Miller was not suffering from any contagious or infectious disease, and that this was untrue, as he and Miss Miller knew , that all three conspired to conceal the state of Mr Miller from the plaintiff, and made false statements with that object Damages to the extent of £250 were awarded Counsel for Mr Harbord asked for judgment for his client *non obstante veredicto*, on the ground that there was no obligation upon him to disclose his patient's condition to the plaintiff and no evidence that he did not believe that in this country leprosy was neither infectious nor contagious After further argument to the effect that there was no evidence to support the jury s findings, Mr Justice Darling gave judgment for the defendants

---

[3] See table on p [illegible] of Registrar-General s return for the fourth quarter of 1915

[4] Published in 1915 by the Cambridge University Press Pp 253 Price [illegible] 6d.

The Court of Appeal has since affirmed the decision of Mr Justice Darling Lord Justice Swinfen Eady held that there is no foundation in law for the argument that there is a warranty or condition that when a person takes furnished rooms he shall not be suffering from any disease which may be infectious or contagious , that there was no evidence that Miss Miller knew that her father was suffering from leprosy or from any infectious or contagious disease With regard to Mr Harbord, the evidence showed that he had nothing to do with the original taking of the rooms , he had told the landlady when questioned by her, that the deceased was not suffering from an infectious disease, but had warned her to be careful and that no one else was to use the lavatory used by the patient According to the evidence, the risk of infection with leprosy in this country was practically *nil* and that was Mr Harbord's view He honestly expressed the opinion that he held, and was under no obligation to divulge to the lodging house keeper anything with regard to his patient Moreover, the plaintiff could have determined the tenancy by giving a week s notice to her tenants His lordship held that in view of the above Mr Justice Darling was right in holding that there was no evidence upon which to base any finding which involved either of the defendants in liability to the plaintiff Lord Justice Bankes in concurring, said "I see no evidence whatever on which it can be suggested as against this medical man that he did not honestly believe that speaking practically, there was no danger either of infection or contagion from this particular disease." The appeal was therefore dismissed That this case should have ended as it did, and that Mr Justice Darling s judgment should have been upheld is eminently satisfactory and the medical profession as well as Mr Harbord is to be congratulated upon the result arrived at The charge made in claiming damages was a charge of deliberate falsehood and conspiracy involving known danger to the health of innocent people for the convenience and in the interest of the medical man's patient It is established that of all this there was no evidence The fact that a case of leprosy was involved with the exposition of medical opinion as to this disease added incidental interest to the trial

Coroners Juries in War Time

Three sane and useful suggestions have been made by Mr S Ingleby Oddie in a letter to the *Times* for economising money and men s time in connexion with inquests He recommends that the coroner should be enabled by an Act of Parliament (1) to hold inquests without a jury, or (2) to hold them with a jury of seven or (3) to order post-mortem examinations before deciding that an inquest is to be held Of these it will probably be agreed by many that the adoption of numbers (1) and (3) not alternatively but simultaneously would be a useful innovation, and if such adoption were to be for the period of the war only would constitute an experiment which need not be continued if it should prove unsuccessful The third suggestion deals with a recommendation often made by coroners which found strong support at the hands of the Departmental Committee on Coroners' Law in 1910 The first should be favourably considered by those who remember that many coroners are, and all might be medical men with sufficient legal training for the performance of a coroner s duties so far as they entail knowledge of law It may be pointed out that the economy of money, time, and man power effected would be on a more important scale than that involved in the recent abolition of reports of certifying surgeons on accidents which had a similar object in view Also it would not involve injustice to anyone whose functions would be dispensed with, or any loss of protection to the persons on whose behalf they are now exercised

The Slingsby Case

In this case a declaration was claimed under the Legitimacy Declaration Act, 1858 with regard to the alleged child of Commander C H R Slingsby It will be remembered that Mr Justice Bargrave Deane found that the child was borne by Mrs Slingsby at San Francisco the allegation on the other side being that he had been procured for her from another woman The Court of Appeal held that the evidence did not justify the finding of Mr Justice Bargrave Deane, and the appeal on behalf of the child to the House of Lords has now been dismissed A curious feature of the case consisted in the calling in of Sir George Frampton, the well known sculptor to express an opinion upon the question of physical resemblance on the part of the child to the parents who claimed him as theirs Sir George Frampton was of the opinion that a strong likeness existed, and the judge appears to have thought so too As to this Lord Loreburn, in the House of Lords, expressed the opinion that Mr Justice Bargrave Deane's views of the evidence must have unconsciously been influenced by Sir George Frampton, while Lord Sumner said that any weight that might be attached to likeness was overborne by other evidence

PUBLIC HEALTH OF MANCHESTER

IN his recently published annual report Dr James Niven gives an instructive account of the health of the city of Manchester in the year 1915 and of the various preventive measures carried out under his direction, special reference being made to the administrative action taken locally for the control of tuberculosis The appearance of this volume shortly after the issue of Dr W H Hamer s report[1] for the same period affords opportunity for comparing the statistical records and sanitary defences of a well equipped provincial city with corresponding data for the metropolis

The recorded death rate" of Manchester was equal to 16 31 per 1000 at all ages, or 1 42 below the decennial average rate The tabular records submitted are less complete than previously and there is great doubt as to the total population of the city Owing to the large number of enlistments, the age constitution of the civil population has seriously changed Nor is this change confined to the male sex, since recent alterations of occupation have affected the distribution of women also Either for reasons of economy, in war time, or else because of uncertainty attaching to population estimates many of the usual tables are omitted in this report But this omission has to some extent been compensated for by the Registrar General, who publishes detailed periodical returns of mortality and of disease notification in each of the great British towns[2]

The national records deal with the entire areas of the several towns but in the present report essential particulars are given for each of the statistical divisions of the city From these we learn that, as compared with the decennial average, the crude death rate in 1915 shows a marked improvement in North Manchester and a considerable improvement in South Manchester, but a falling off in the old Manchester township This supports the conclusion previously reached that the poorer classes have suffered disproportionally in the last two years Nevertheless, the average position of the Manchester working classes is believed to have improved, and there has been less pauperism in 1915 than in the two preceding years In order to avoid the uncertainty attaching to estimates of population the actual deaths (in place of the death rates) from the chief causes in the last three years are summarised in an instructive table The most striking feature in this table is the great increase in the deaths from tuberculous phthisis and from heart disease in 1915, as compared with the year preceding the war This abrupt rise especially in the case of the first-named disease, may be due in part to the strain induced by war conditions and in part to the lack of new dwellings for the growing population. Towards the close of last century a national movement was initiated for the suppression of tuberculosis In a recent classical work[4] entitled " A Campaign against Consumption " by the late Dr Arthur Ransome then professor of public health in the Victoria University the history of that movement was traced to its local origin half a century ago The author asserts that the honour of being the first authority to suggest and eventually to adopt measures for the suppression of this scourge may fairly be claimed by Manchester Dr Ransome's own entrance into the campaign dates back to the year 1860, and to the establishment in Manchester and Salford of a weekly return of common diseases, prominent among which was phthisis There is good reason to believe that these returns voluntarily contributed by about 30 medical residents for more than 12 consecutive years were not merely the forerunners but powerful incentives to the more complete notification returns which are now everywhere required under statute law In 1884 a large area of old and dilapidated dwellings in Ancoats was officially condemned as unfit for human habitation. This area was supposed to afford shelter for 5600 persons of the poorest class who on a five years average were succumbing to phthisis at the rate of 5 3 per 1000 living The buildings on this area and other insanitary areas in the older parts of the city have recently been demolished by the municipality and better house accommodation has been provided for the displaced occupants

Notification of tuberculous phthisis—Dr Niven will be recognised by his medical colleagues generally as one of the earliest among advocates of the compulsory notification of phthisis as well as of its preventive treatment, as a matter of State policy He is to be congratulated on the large measure of success he has achieved in Manchester in dealing with the administrative difficulties of the crusade—difficulties which were at one time regarded as insurmountable by many of his contemporaries Systematic notification of phthisis is still on its trial in Manchester London and some other towns and as local experience accumulates the results should materially influence administrative action In the present report there appears a standard table showing the number of primary notifications during the year This table is identical in form with that contained in Dr Hamer s London report, and we may presume that the respective health officers will avail themselves of this and similar methods for the comparison of future results The usual table showing the facts and rates of notification in the several districts has been prepared for 1915, but is not inserted in this report The *notification rate* exceeds the *death-rate* in various degrees The case of Withington is especially notable In this residential district the deaths steadily outnumber the reported cases, pointing to a failure in the duty of notification The earliest records available respecting the results of notification are those for 1899—since which year more than 28,000 phthisical patients have been visited by the staff In 25,000 cases sputum has been examined with positive results in one third of the cases Not fewer than 27 106 of the patients have been isolated in hospital and the houses disinfected after removal of the patients

The loss of life from phthisis in 1915 was in excess of the average It was 1 76 per 1000 living of both sexes at all ages, and was above the mean rate in the preceding ten years by 0 09 per 1000 It was also above the rate in the County of London by 0 16 per 1000 When the total deaths in a single year are distributed over several age groups in both sexes the *rate of mortality* for each separate group cannot usefully be compared with corresponding rates for previous years Nevertheless the *number of deaths* at each age may properly be compared, and thus an approximate idea of the course of events may be presented By this means we learn that *among males* the phthisis deaths were more numerous in 1915 than in any of the preceding ten years (This statement relates exclusively to the civil population, which includes Manchester soldiers discharged on account of phthisis) The most marked increase occurs at ages 15–19, 20–24 and 35–74 but not at ages 25–34 nor at ages under 15 *Among females* also there is a corresponding excess in the deaths, the increase being nearly as great as among males The greatest increase occurs at ages 25–34 It is possible that the additional stress of work now thrown on both sexes, and the inordinate demand for workers in the prime of life may account for the great addition to the death toll When the deaths from bronchitis are examined similarly, they present parallel rises to those from phthisis both among males and females Pneumonia shows no such increase, on the contrary among males the deaths thus returned in 1915 were fewer than in any of the preceding ten years Among females they were fewer than in any of the ten except 1906

Milk and tuberculosis—The milk supply of Manchester is derived from about 69 farms chiefly in the counties of Cheshire Derbyshire, Staffordshire, and Lancashire During the year 91 samples of milk were examined and in a useful table the percentages are given of farmers in each county whose milk was found to cause tuberculosis. It is noteworthy that none of the farmers in Derbyshire or in Staffordshire sent tuberculous milk to the city In Dr Niven s report for 1913 particulars were given of the successful manner in which the work of keeping a herd of cows free from tuberculosis is being carried on The milk produced by this herd is still supplied to the large fever hospital at Monsall and to the sanatorium at Baguley

Poverty in relation to phthisis—A most instructive table is inserted giving a classification of the cases whose family income fell short of a standard rate according to the ascertained "shortage ' and showing the institutional assistance obtained for these patients The standard was based on that given by Mr B Rowntree in his book on poverty The table indicates under several headings the numbers living and the numbers dead at the end of 1915 the numbers admitted to the several hospitals and the number receiving institutional assistance It would appear from this table that in 1915 phthisis was more fatal to the poorer classes of cases than in previous years

Report of the Tuberculosis Officer

A valuable report by Dr D P Sutherland is appended to that of the medical officer of health It contains minute details of the manifold operations of his department in the course of the year We can only briefly refer to the analysis of cases in which the results of institutional and dispensary treatment are shown In the "residential

that the father the daughter and Mr Harbord concealed the fact from the plaintiff in consequence of which the rooms were let. After a great deal of evidence had been given the jury returned answers in the plaintiff's favour to all the questions put to them finding as facts that Mr Miller when he took the rooms was liable to infect persons and furniture with leprosy, and that he and his daughter knew it, that the disease was communicable by infection or contagion in England, that Miss Miller and Mr Harbord fraudulently misrepresented Mr Miller as fit to occupy the rooms, that they concealed from the plaintiff that Mr Miller was suffering from a disease which made him unfit and dangerous to occupy the rooms, that Mr Harbord acting as agent for the other two, stated that Mr Miller was not suffering from any contagious or infectious disease and that this was untrue as he and Miss Miller knew, that all three conspired to conceal the state of Mr Miller from the plaintiff and made false statements with that object. Damages to the extent of £250 were awarded. Counsel for Mr Harbord asked for judgment for his client *non obstante veredicto* on the ground that there was no obligation upon him to disclose his patient's condition to the plaintiff and no evidence that he did not believe that in this country leprosy was neither infectious nor contagious. After further argument to the effect that there was no evidence to support the jury's findings, Mr Justice Darling gave judgment for the defendants.

[3] See table on p 41 of Registrar-General s return for the fourth quarter of 1915

[4] Published in 1915 by the Cambridge University Press Pp 263 Price 10s 6d

The Court of Appeal has since affirmed the decision of Mr Justice Darling. Lord Justice Swinfen Eady held that there is no foundation in law for the argument that there is a warranty or condition that when a person takes furnished rooms he shall not be suffering from any disease which may be infectious or contagious that there was no evidence that Miss Miller knew that her father was suffering from leprosy or from any infectious or contagious disease. With regard to Mr Harbord the evidence showed that he had nothing to do with the original taking of the rooms, he had told the landlady when questioned by her that the deceased was not suffering from an infectious disease but had warned her to be careful and that no one else was to use the lavatory used by the patient. According to the evidence, the risk of infection with leprosy in this country was practically *nil* and that was Mr Harbord's view. He honestly expressed the opinion that he held and was under no obligation to divulge to the lodging house keeper anything with regard to his patient. Moreover, the plaintiff could have determined the tenancy by giving a week's notice to her tenants. His lordship held that in view of the above Mr Justice Darling was right in holding that there was no evidence upon which to base any finding which involved either of the defendants in liability to the plaintiff. Lord Justice Bankes in concurring said 'I see no evidence whatever on which it can be suggested as against this medical man that he did not honestly believe that speaking practically there was no danger either of infection or contagion from this particular disease. The appeal was therefore dismissed. That this case should have ended as it did, and that Mr Justice Darling's judgment should have been upheld is eminently satisfactory and the medical profession as well as Mr Harbord is to be congratulated upon the result arrived at. The charge made in claiming damages was a charge of deliberate falsehood and conspiracy involving known danger to the health of innocent people for the convenience and in the interest of the medical man's patient. It is established that of all this there was no evidence. The fact that a case of leprosy was involved with the exposition of medical opinion as to this disease added incidental interest to the trial.

Coroners' Juries in War Time

Three sane and useful suggestions have been made by Mr S Ingleby Oddie in a letter to the *Times* for economising money and men's time in connexion with inquests. He recommends that the coroner should be enabled by an Act of Parliament (1) to hold inquests without a jury, or (2) to hold them with a jury of seven or (3) to order post-mortem examinations before deciding that an inquest is to be held. Of these it will probably be agreed by many that the adoption of numbers (1) and (3) not alternatively but simultaneously would be a useful innovation, and if such adoption were to be for the period of the war only would constitute an experiment which need not be continued if it should prove unsuccessful. The third suggestion deals with a recommendation often made by coroners which found strong support at the hands of the Departmental Committee on Coroners Law in 1910. The first should be favourably considered by those who remember that many coroners are, and all might be medical men with sufficient legal training for the performance of a coroner's duties so far as they entail knowledge of law. It may be pointed out that the economy of money time and man power effected would be on a more important scale than that involved in the recent abolition of reports of certifying surgeons on accidents, which had a similar object in view. Also it would not involve injustice to anyone whose functions would be dispensed with or any loss of protection to the persons on whose behalf they are now exercised.

The Slingsby Case

In this case a declaration was claimed under the Legitimacy Declaration Act 1858 with regard to the alleged child of Commander C H R Slingsby. It will be remembered that Mr Justice Bargrave Deane found that the child was borne by Mrs Slingsby at San Francisco the allegation on the other side being that he had been procured for her from another woman. The Court of Appeal held that the evidence did not justify the finding of Mr Justice Bargrave Deane and the appeal on behalf of the child to the House of Lords has now been dismissed. A curious feature of the case consisted in the calling in of Sir George Frampton the well known sculptor to express an opinion upon the question of physical resemblance on the part of the child to the parents who claimed him as theirs. Sir George Frampton was of the opinion that a strong likeness existed, and the judge appears to have thought so too. As to this Lord Loreburn in the House of Lords expressed the opinion that Mr Justice Bargrave Deane's views of the evidence must have unconsciously been influenced by Sir George Frampton while Lord Sumner said that any weight that might be attached to likeness was overborne by other evidence.

PUBLIC HEALTH OF MANCHESTER

In his recently published annual report Dr James Niven gives an instructive account of the health of the city of Manchester in the year 1915 and of the various preventive measures carried out under his direction special reference being made to the administrative action taken locally for the control of tuberculosis. The appearance of this volume shortly after the issue of Dr W H Hamer's report[1] for the same period affords opportunity for comparing the statistical records and sanitary defences of a well equipped provincial city with corresponding data for the metropolis.

The recorded death rate of Manchester was equal to 16 31 per 1000 at all ages, or 1 42 below the decennial average rate. The tabular records submitted are less complete than previously and there is great doubt as to the total population of the city. Owing to the large number of enlistments the age constitution of the civil population has seriously changed. Nor is this change confined to the male sex since recent alterations of occupation have affected the distribution of women also. Either for reasons of economy, in war time, or else because of uncertainty attaching to population estimates many of the usual tables are omitted in this report. But this omission has to some extent been compensated for by the Registrar General who publishes detailed periodical returns of mortality and of disease notification in each of the great British towns.[2]

The national records deal with the entire areas of the several towns, but in the present report essential particulars are given for each of the statistical divisions of the city. From these we learn that, as compared with the decennial average, the crude death rate in 1915 shows a marked improvement in North Manchester and a considerable improvement in South Manchester, but a falling off in the old Manchester township. This supports the conclusion previously reached, that the poorer classes have suffered disproportionally in the last two years. Nevertheless, the average position of the Manchester working classes is believed to have improved and there has been less pauperism in 1915 than in the two preceding years. In order to avoid the uncertainty attaching to estimates of population, the actual deaths (in place of the death rates) from the chief causes in the last three years are summarised in an instructive table The most striking feature in this table is the great increase in the deaths from tuberculous phthisis and from heart disease in 1915, as compared with the year preceding the war This abrupt rise especially in the case of the first-named disease, may be due in part to the strain induced by war conditions and in part to the lack of new dwellings for the growing population. Balancing the gains and losses of life during 1915 in comparison with those in the previous ten years, the largest gains are found to be under the heads of pneumonia, whooping cough, nervous disease, and diarrhœa The losses are greatest under the heads of cancer, heart disease, and old age

[2] The Lancet 1916 ii 1024

Infantile mortality—Inasmuch as the mortality in the first year after birth is based, not on the numbers estimated to be living at that age, but on the number of infants born alive during the year, it is obviously unaffected by uncertainties as to population It is also independent of the birth rate In the year under notice infant mortality in Manchester was at the rate of 129 per 1000 births, as compared with 112 in London 117 in the 96 great towns and 110 in England and Wales [3] Infant mortality in the first three months of life was lower than in any previous years It was also low in the second three months, but in the last half of the first year it was comparatively high Compared with the preceding three years, we learn that during the first three months after birth proportionally fewer deaths occurred in 1915 from convulsions premature birth atrophy, and suffocation—i e, from that class of disease which it is our main object to prevent In the second three months the relation is less favourable During the last half of the first year of life there were in 1915 relatively fewer deaths from whooping cough, tuberculosis, and convulsions but relatively more from measles, diphtheria lung disease and violence the excess under lung disease being probably determined by measles prevalence

Administrative Control of Pulmonary Tuberculosis

Towards the close of last century a national movement was initiated for the suppression of tuberculosis In a recent classical work [4] entitled "A Campaign against Consumption" by the late Dr Arthur Ransome then professor of public health in the Victoria University the history of that movement was traced to its local origin half a century ago The author asserts that the honour of being the first authority to suggest and eventually to adopt measures for the suppression of this scourge may fairly be claimed by Manchester Dr Ransome s own entrance into the campaign dates back to the year 1860, and to the establishment in Manchester and Salford of a weekly return of common diseases, prominent among which was phthisis There is good reason to believe that these returns voluntarily contributed by about 30 medical residents for more than 12 consecutive years, were not merely the forerunners but powerful incentives to the more complete notification returns which are now everywhere required under statute law In 1884 a large area of old and dilapidated dwellings in Ancoats was officially condemned as unfit for human habitation. This area was supposed to afford shelter for 5600 persons of the poorest class who on a five years average were succumbing to phthisis at the rate of 5 3 per 1000 living The buildings on this area, and other insanitary areas in the older parts of the city have recently been demolished by the municipality and better house accommodation has been provided for the displaced occupants

Notification of tuberculous phthisis—Dr Niven will be recognised by his medical colleagues generally as one of the earliest among advocates of the compulsory notification of phthisis as well as of its preventive treatment, as a matter of State policy He is to be congratulated on the large measure of success he has achieved in Manchester in dealing with the administrative difficulties of the crusade—difficulties which were at one time regarded as insurmountable by many of his contemporaries Systematic notification of phthisis is still on its trial in Manchester London and some other towns and as local experience accumulates the results should materially influence administrative action In the present report there appears a standard table showing the number of primary notifications during the year This table is identical in form with that contained in Dr Hamer's London report, and we may presume that the respective health officers will avail themselves of this and similar methods for the comparison of future results The usual table showing the facts and rates of notification in the several districts has been prepared for 1915, but is not inserted in this report The *notification rate* exceeds the *death rate* in various degrees The case of Withington is especially notable In this residential district the deaths steadily outnumber the reported cases, pointing to a failure in the duty of notification The earliest records available respecting the results of notification are those for 1899—since which year more than 28,000 phthisical patients have been visited by the staff In 25,000 cases sputum has been examined, with positive results in one third of the cases Not fewer than 27 106 of the patients have been isolated in hospital and the houses disinfected after removal of the patients

The loss of life from phthisis in 1915 was in excess of the average It was 1 76 per 1000 living of both sexes at all ages, and was above the mean rate in the preceding ten years by 0 09 per 1000 It was also ab ve the rate in the County of London by 0 16 per 1000 When the total deaths in a single year are distributed over several age groups in both sexes the *rate of mortality* for each separate group cannot usefully be compared with corresponding rates for previous years Nevertheless the *number of deaths* at each age may properly be compared, and thus an approximate idea of the course of events may be presented By this means we learn that *among males* the phthisis deaths were more numerous in 1915 than in any of the preceding ten years (This statement relates exclusively to the civil population, which includes Manchester soldiers discharged on account of phthisis) The most marked increase occurs at ages 15–19, 20–24, and 35–74 but not at ages 25–34, nor at ages under 15 *Among females* also there is a corresponding excess in the deaths, the increase being nearly as great as among males The greatest increase occurs at ages 25–34 It is possible that the additional stress of work now thrown on both sexes, and the inordinate demand for workers in the prime of life may account for the great addition to the death toll When the deaths from bronchitis are examined similarly, they present parallel rises to those from phthisis both among males and females Pneumonia shows no such increase, on the contrary among males the deaths thus returned in 1915 were fewer than in any of the preceding ten years Among females they were fewer than in any of the ten except 1906

Milk and tuberculosis—The milk supply of Manchester is derived from about 69 farms chiefly in the counties of Cheshire Derbyshire, Staffordshire, and Lancashire During the year 91 samples of milk were examined and in a useful table the percentages are given of farmers in each county whose milk was found to cause tuberculosis It is noteworthy that none of the farmers in Derbyshire or in Staffordshire sent tuberculous milk to the city In Dr Niven's report for 1913 particulars were given of the successful manner in which the work of keeping a herd of cows free from tuberculosis is being carried on The milk produced by this herd is still supplied to the large fever hospital at Monsall and to the sanatorium at Baguley

Poverty in relation to phthisis—A most instructive table is inserted giving a classification of the cases whose family income fell short of a standard rate according to the ascertained "shortage" and showing the institutional assistance obtained for these patients The standard was based on that given by Mr B Rowntree in his book on poverty The table indicates under several headings the numbers living and the numbers dead at the end of 1915 the numbers admitted to the several hospitals and the number receiving institutional assistance It would appear from this table that in 1915 phthisis was more fatal to the poorer classes of cases than in previous years

Report of the Tuberculosis Officer

A valuable report by Dr D P Sutherland is appended to that of the medical officer of health It contains minute details of the manifold operations of his department in the course of the year We can only briefly refer to the analysis of cases in which the results of institutional and dispensary treatment are shown In the "residential

department" 955 cases were treated in the several institutions, of which 505 were discharged "improved," 92 "without improvement," and 76 died. At the end of the year 221 cases remained under treatment. In the dispensary department 502 cases were treated, 212 of which were discharged as improved and 93 as without improvement, whilst 11 died. At the end of the year 132 patients still remained under treatment. Dr. Sutherland concludes his report with the encouraging statement that during the year 152 insured notified cases were found to have so far recovered that no evidence of active tuberculosis could be demonstrated; these are therefore to be regarded as arrested cases. They will, however, still remain under observation, and their health and working capacity will be reported upon periodically.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Annual Report of the Local Government Board for Ireland.

THE annual report of the Local Government Board for the year ending March 31st, 1916, is a slim pamphlet of some 60 pages instead of the portly volume to which we have been accustomed. This economy of paper and printing has been effected by the omission of the multitudinous tables and returns which used to appear as appendices to the report proper. The tables, though not published, have been prepared as usual and are available for reference. The figures relative to poor relief show a rising improvement. The numbers in workhouses, including sick, aged, and infirm, lunatics, idiots, and imbeciles, have decreased markedly, while the numbers in the extern institutions, and more especially those receiving outdoor relief, have diminished both individually and in the aggregate. In the workhouses the deaths have decreased by 581 on the number of the previous year, and the total number of deaths from tuberculosis have decreased by 167, thus keeping up the record of diminution which has existed without a break since 1912. The deaths of infants show a decrease of 272. A graceful tribute is paid in the report to the large number of medical officers who have volunteered for service with the forces of the Crown, while the difficulty of finding adequate assistance in caring and attending on the sick poor is also commented on. The notification of tuberculosis is being gradually extended, and some local bodies have passed resolutions in favour of the general introduction of the system. The report announces with regret that "notification is not infrequently delayed until a late stage in the disease," and asks that care should be taken in all cases to notify before the infection has reached an advanced stage. Unfortunately the Local Government Board ignores that under the conditions prescribed by the Board itself for the notification of tuberculosis it is only rarely that it is legal to notify the disease in the early stages. A medical man notifying the disease except under the prescribed conditions would leave himself open to an action for damages. In speaking of its care of the Belgian refugees thanks are given to the medical men and the hospitals of Dublin for the free advice and treatment rendered during the year.

Doctors of Military Age in Ireland.

The legal adviser of the Irish Local Government Board, Dr. Vanston, K.C., has given his opinion that the Board had an absolute discretion under Section 8 of the Act 14 and 15 Vict., cap. 68, to refuse their approval as they thought proper for any reason or without giving any reason to the appointment of a medical officer of a dispensary district made pursuant to statute by a board of guardians. Further, Dr. Vanston states that the Letterkenny board of guardians have no power to remove Dr. Walker from the office of temporary medical officer by passing the resolution of Sept. 8th, 1916, which was *ultra vires* and of no legal effect. In the face of these facts, communicated by the Local Government Board, the Letterkenny board of guardians, by a motion passed by a majority at their last weekly meeting, have decided to instruct their solicitor to take the necessary proceedings to compel the Local Government Board to sanction Dr. J. P. McGinley's appointment.[1]

Infectious Diseases in Ireland.

The following table in regard to infectious diseases in Ireland appeared in one of the Belfast papers of Dec. 28th, 1916. These are notifications:—

Dublin. Week ending—	Scarlet fever.	Diphtheria.	Enteric fever.	Erysipelas.	Total notifications.	*Belfast.* Week ending—	Scarlet fever.	Diphtheria.	Enteric fever.	Erysipelas.	Total notifications.
Nov. 18th	8	3	8	1	25	Nov. 18th	22	4	9	7	43
Nov. 25th	5	1	6	3	21	Nov. 25th	10	5	6	4	25
Dec. 2nd	7	3	2	0	20	Dec. 2nd	15	4	4	3	26
Dec. 16th	3	3	2	3	15	Dec. 16th	14	3	5	5	26
Total	23	10	18	7	81	Total ...	61	16	24	19	122

The disease "tuberculous phthisis" is now omitted. The anomalous figures under this heading were made the subject of comment in THE LANCET when it was pointed out that while only a few cases of phthisis were as a rule notified in Belfast, quite a number of notifications appeared in the Dublin list. The explanation, if such it can be called, is said to be the difficulty of notification in Ireland to which allusion has been made. The disappearance of the figures from the official table does not lessen the difficulty.

Jan. 6th.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

To be temporary Surgeons: A. Orr Ewing and R. Cripps.

Surg. J. R. Haldane is placed on the Retired List.

ARMY MEDICAL SERVICES

TERRITORIAL FORCE.

Capt. A. N. S. Carmichael, from attached to Units other than Medical Units, to be Deputy Assistant Director of Medical Services.

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. I. Brodribb is restored to the establishment.

To be temporary Lieutenant-Colonels: Col. V. Matthews, late R.A.M.C. (T.F.), whilst specially employed; and H. M. Rigby (Capt. R.A.M.C., T.F.).

W. I. Home, Fleet Surgeon, R.N. (ret.), to be temporary Major.

To be temporary Honorary Majors: R. Armstrong-Jones and L. W. White.

To be temporary Captains: Temp. Lieut. F. W. H. Hutchinson, C. G. Whorlow, R. Williams, and C. H. Treadgold.

To be Lieutenant: R. Mountain.

To be temporary Lieutenants: J. K. Watson, C. D. H. Corbett, A. B. Goldie, H. H. Halifax, S. G. J. Dowling, A. C. S. Waters, E. B. White, F. C. Sprawson, F. Simpson, W. F. Gibb, C. M. Atkinson, A. G. Macdonald, A. B. McMaster, F. Challans, C. L. Tangye, P. J. O'Sullivan, J. A. Leighton, M. J. A. Wallis, R. O. Whyte, L. B. C. Trotter, I. G. Cobb, C. K. Smith, J. H. Mayston, H. Freeth, A. Leitch, J. Young, M. H. Raper, T. H. Macfie, B. A. Slocombe, M. Henry, O. L. Williams, and H. O. Peel.

Temporary Captains relinquishing their commissions: J. Burfield, R. J. Jones, and T. P. Weakliam (on account of ill health).

Lieutenants relinquishing their commissions: F. J. R. Forster, J. D. Shiels, W. K. O'Gorman, and M. F. Hession.

TERRITORIAL FORCE.

Capt. B. Robertshaw, from a Field Ambulance, to be Captain.

Capt. H. M. Rigby, Capt. J. O. Macnamara, and Capt. A. D. Reid are seconded whilst holding temporary commissions in the R.A.M.C.

Capt. J. M. Hunt to be temporary Major.

Capt. H. G. I. Dawson to be Major.

Lieutenants to be Captains: F. F. T. Hare, S. Child, and O. P. Sells.

Capt. (temp. Major) J. F. W. Mac Fall relinquishes his temporary rank on ceasing to command a Field Ambulance.

Capt. (temp. Major) J. Young to be temporary Lieutenant-Colonel whilst commanding a Field Ambulance.

Lieut.-Col. F. J. Knowles, from Territorial Force Reserve, to be Lieutenant-Colonel without pay or allowances.

Capt. F. B. Smith, from a Field Ambulance, to be Captain.

Lieut. J. C. Newman to be Captain.

Captains relinquishing their commissions: E. P. Dawes, W. H. Calvert, and B. S. Wills.

TERRITORIAL FORCE RESERVE.

Capt. W. N. W. West Watson, from a casualty clearing station, to be Captain.

SPECIAL RESERVE OF OFFICERS.

Lieut. (on probation) R. R. Scott is confirmed in his rank.

INDIAN MEDICAL SERVICE

Temporary Lieutenants to be temporary Captains: Kamberanda Kalapa Mandara and Johangir Kaikhusro Nariman.

The retirement of Capt. Jogesh Chandra Dey has been confirmed by the King.

---

[1] See THE LANCET, 1916, ii., 497.

Col W W Clemesha, Sanitary Commissioner with the Government of India, is at present working temporarily as health officer of Delhi pending the arrival of a permanent incumbent

DEATHS IN THE SERVICES

Surgeon-General Sir Edmond Townsend, K C B C M G , A M S , on Jan 3rd at his residence, Clontymon Co Cork aged 71 after a long record of active service He entered the Army in 1867 and served in the Abyssinian campaign 1867–68 (medal) in the Malay Peninsula 1875–76 where he was severely wounded (medal with clasp) and in the Zulu war where he was present at the battle of Alundi in 1879 (mentioned in despatches) He also served in the Egyptian war of 1882, including Kassassin, Tel-el Kebir (medal with clasp and Khedive s Star) in the Burmese Expedition 1885-86 (medal with clasp) and in the Ashanti Expedition (mentioned in despatches and star) He was with the forces in the North Western Frontier of India campaign 1897-98, Principal Medical Officer with the Mohmund Field Force and Principal Medical Officer with the 1st Division in the Tirah Expeditionary Force (mentioned in despatches, C B and medal with two clasps) In the South Africa n war of 1899–1902 he was Principal Medical Officer with the 1st Division and afterwards in the Western District (dangerously wounded. mentioned in despatches C M G Queen s medal with four clasps, and King's medal with two clasps) From 1902 till his retirement from the service in 1905 he was Principal Medical Officer at Netley

VITAL STATISTICS

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns 959 births and 872 deaths were registered during the week ended Saturday Dec. 30th 1916 The annual rate of mortality which had increased from 13 8 to 19 6 per 1000 in the four preceding weeks fell to 19·2 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death rate in these towns averaged 15 3 against 15·6 per 1000 in the large English towns. Among the several towns the death rate during the week ranged from 9 3 in Ayr 11 4 in Leith and 13 7 in Clydebank to 23·0 in Perth, 26 7 in Hamilton, and 26 9 in Dundee

The 872 deaths from all causes were 20 fewer than the number in the previous week and included 50 which were referred to the principal epidemic diseases against 37 and 46 in the two preceding weeks Of these 50 deaths, 13 resulted from infantile diarrhœal diseases 11 each from whooping cough and diphtheria, 10 from measles 3 from scarlet fever and 2 from enteric fever The annual death rate from these diseases was equal to 1 1 against 0·7 per 1000 in the large English towns. The deaths from infantile diarrhœa, which had been 14 10 and 9 in the three preceding weeks rose to 13 of which 9 occurred in Glasgow The deaths referred to diphtheria, which had been 6 3 and 6 in the three preceding weeks rose to 11 and included 4 in Glasgow and 2 each in Edinburgh and Dundee The fatal cases of whooping-cough which had been 3 7 and 12 in the three preceding weeks numbered 11 and comprised 4 in Glasgow 3 in Edinburgh and 2 in Leith The deaths attributed to measles, which had been 12 11 and 14 in the three preceding weeks fell to 10 of which 8 occurred in Dundee The 3 deaths from scarlet fever were slightly below the average in the earlier weeks of the quarter The 2 fatal cases of enteric fever occurred in Glasgow

The deaths referred to diseases of the respiratory system which had increased from 118 to 227 in the four preceding weeks further rose to 240 in the week under notice and were 85 above the number registered in the corresponding week of 1915 The deaths from violence numbered 27 against 34 and 33 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the registration area of Dublin 130 births and 216 deaths were registered during the week ended Saturday Dec. 30th 1916. The annual rate of mortality which had increased from 17·7 to 25·6 per 1000 in the four preceding weeks further rose to 28 4 in the week under notice against 23·7 per 1000 in London

The 216 deaths from all causes included 24 of infants under 1 year and 73 of persons aged 65 years and upwards Five deaths were referred to infantile diarrhœa 4 to measles, 2 to whooping-cough and 1 to scarlet fever The causes of 19 deaths were uncertified and those of 9 others were the subject of coroners inquests while 79 or 37 per cent of the total deaths occurred in public institutions

During the same period 133 births and 159 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 21 3 per 1000 and included 14 of infants under 1 year and 52 of persons aged 65 years and upwards Two deaths were referred to infantile diarrhœa and 1 each to measles and diphtheria The causes of 5 deaths were uncertified 8 inquests were held and 39 of the total deaths occurred in public institutions

RUSSIAN MEDICAL SCHOLARSHIPS —The director of the Higher Institute of Medicine for Women at Petrograd has received an anonymous gift of £20 000 for the foundation of scholarships in the name of Count Vorontzoff, who died last year

CENTENARIANS —Mrs Elizabeth Symons, of Church Town Crowan died recently, aged 102 years and 10 months She is stated to have been the oldest person in Cornwall —Mr Samuel Stidwill of 6 Union street, Stonehouse Plymouth died on Dec 26th, 1916, aged 102 years —Mrs Harriet Godland died recently at an almshouse in Ilton, Dorset in her 104th year —Mrs Mary M Quade Omeath S Louth, died on Jan 4th at the remarkable age of 110 years She spoke English and Irish fluently and is said to have been the oldest woman in Ireland She resided all her life at Omeath and her age has—it is stated in the papers—been verified by church records

THE LIQUOR TRAFFIC AND THE FOOD QUESTION

To the Editor of THE LANCET

SIR,—In your leading article under this title you comment on the effect of the regulations of the Liquor Control Board in decreasing drunkenness and alcoholic disease as measured by the most characteristic manifestation of alcoholism, delirium tremens In the report of the Liquor Control Board, issued a few days ago, statistics are given which show a reduction in the number of female convictions for drunkenness of 43 8 per cent in England and 37 7 per cent in Scotland, and the Board regards these figures as effectively disproving the common assertion that, while drunkenness among men may have diminished it has increased among women My experience as physician in charge of the alcoholic wards in the Royal Infirmary, Edinburgh leads me to believe that there is an important fallacy in the data founded on , and it is in the public interest at the present time that attention should be drawn to it

During the past year there has been a very unusual strain on the wards in question and more especially for female patients The number of patients suffering from acute alcoholism—nearly all brought in by the police—who were sufficiently ill to necessitate their being treated as in patients was double the average of previous years The accompanying table shows the record for admission of men and women, and also the number of women arrested for drunkenness during the same period —

	Admissions to wards		Arrests for drunkenness
	Males	Females	Females
1913	198	52	1719
1914	185	51	1961
1915	169	53	1721
1916	151	103	1222

This increase in alcoholic cases is confirmed in the experience of the out-patient department of the hospital where less serious cases are treated for injuries received under the influence of liquor , statistics on this point are not, however, available, as the patients are classified according to the surgical conditions

We have therefore, an anomalous position, the experience of the hospital pointing conclusively to a marked increase of alcoholism among women , the statistics of the police under the headings of "Convictions for Drunkenness" and "Arrest for Drunkenness" pointing in the opposite direction

If the experience in Edinburgh can be taken as an index of conditions obtaining elsewhere, it seems clear that the Liquor Control Board is hardly justified in the conclusion it has drawn from the data supplied by the police reports I am aware that in former reports the Liquor Control Board has given statistics in regard to admissions for delirium tremens mostly, I think in English hospitals In this connexion it is important to keep in mind that in Scotland at any rate only a proportion, and a small one, of cases of acute alcoholism come into the category of delirium tremens

I am, Sir, yours faithfully,

Edinburgh, Jan. 8th 1917 CHALMERS WATSON, M D Edin

⁂ The curious discrepancy to which Dr Chalmers Watson calls attention is explained by the Prison Commissioners, to whose report we allude in another column Fewer women have been convicted of drunkenness, but the average number of convictions per individual has risen to such an extent as actually to increase the total number of convictions —ED L

To the Editor of THE LANCET

SIR —I have read the leading article on the liquor traffic and the food question, in which you comment adversely on total prohibition In the first place you say its enforcement would not be easy Why not? If the conscription of our sons has been attained, why not the conscription of our luxuries? It is the easiest and only way of solving the liquor question; all else is mere tinkering with the evil. Secondly, you put up a problematical case of evil resulting from the sudden cessation of alcohol, especially in elderly men who have been accustomed to it, and dwell on the possibility of restricted output on this account. This theoretical diminution, which I dispute, would be a mere drop in the bucket compared to the actual diminution which is at present going on in munition works from over-indulgence in alcohol by workers who carry it in and had opportunities to consume it at their work. Prohibition would undoubtedly vastly increase the output of war munitions, at least in Glasgow and Clyde district. Your third argument against prohibition is the use of other substances—methylated spirit, varnish, lacquer, and the poisonous effects on those who drink them. Why should we distress ourselves about these degenerates who will not deny their appetites? Is it for the protection and preservation of this portion of our race that we are sending our sons into battle?

Your alternative to prohibition of imposing restrictions in the hours of sale and quality of liquor as advocated by the Liquor Control Board has been a complete failure in Scotland. In to-day's *Glasgow Herald* an Edinburgh doctor gives statistics showing that in the Royal Infirmary there the number of acute alcoholic cases admitted to the female ward was twice as great as in 1913-14, although the convictions for drunkenness in the police courts had fallen by 500. A publican patient of mine tells me that he is quite satisfied with the restricted hours of sale, as he is selling a half more liquor than before it with less labour and expense. The long queues of women seen in Glasgow last week waiting to get bottles filled before the New Year closing day show the utter futility of these restrictions, and the after results are seen in our own Royal Infirmary, where probably one half of the surgical cases are the direct result of alcoholic indulgence. When you know of women admitted there this week with their faces trampled on by drunken husbands, and another jumping out a second storey window to escape from the violence of a drunken madman, you can only conclude that the total prohibition of alcohol is the only efficient way.

If a new disease were to make its appearance in the land bringing in its train one tithe of the wastage and suffering to innocent people that alcohol does, it would not be tolerated for a moment. State ownership would not cure the drinking habits of Scotland—they don't care who owns the public house; their object is to get enough to make them feel the effects of the alcohol. Till we as a nation get a Government that will help us to purge ourselves from our national sins, we cannot hope, nor do we deserve, to win the war.

I am, Sir, yours faithfully,
JAMES DUNLOP, M.B., C.M. Glasg.

Glasgow, Jan. 6th, 1917.

*** No one controverts much of what Dr. Dunlop says, on which we did not comment adversely. It is common knowledge. The enforcement of prohibition is difficult because a vested interest, subject to good conduct, has been recently conferred upon owners of licensed properties. The actual circumstances have to be looked at, lest in the search for what may later be the best we lose the present good.—ED. L.

AGGLUTINATION REACTIONS IN TYPHOID AND PARATYPHOID FEVERS

To the Editor of THE LANCET.

SIR,—It would appear from recent publications that Dreyer, Ainley Walker, and Gibson are of opinion that they were the first to realise the fact that repeated agglutination tests are necessary before arriving at a definite diagnosis in cases of the enteric group in inoculated men.

In a paper published by them in THE LANCET, 1915, i., 324, they made the following statement when dealing with this subject:—

> It is probable that the absence of accurate diagnosis in the past explains the fact that statistical results arrived at in our Army have not always been so convincing as would otherwise have been the case.

The above remark is quite untrue of later years and an injustice to officers of the Royal Army Medical Corps.

I feel that it is only right to point out that repeated observations by the macroscopic method of the serum agglutinin content in cases of suspected typhoid and paratyphoid fevers have been taught at the Royal Army Medical College and carried out by Army bacteriologists since the re-introduction of typhoid inoculation in the Army in 1905.

The necessity for using Dreyer's technique to arrive at reliable results, as suggested in a paper by Ainley Walker in THE LANCET of Nov. 25th, 1916, is not apparent, and equally reliable results can be and have been obtained when using a living suspension of bacilli, provided the suspension is standardised.

The following extracts will show that repeated observations were found to be necessary in past years, and it will be noted that these extracts are from reports and papers published some time before the appearance of papers by Dreyer, Ainley Walker, and Gibson, in fact before they had probably had very many opportunities of noting the serum reactions in inoculated individuals suffering from fevers of the enteric group, especially in the case of paratyphoid A fever, which rarely found its way west of Suez before this war.

The first is from an abstract of report on the enteric fever depot at Naini Tal, taken from the annual reports of divisional sanitary officers in India for 1908, published in 1909:—

> Some of these errors in diagnosis are due to the fact that the men had been inoculated and therefore their blood gave a positive Widal reaction, and they were diagnosed enteric fever on the strength of this alone. In all cases of fever in inoculated men the blood should be taken near the beginning and towards the end of the fever. If the two results are the same the case is probably not enteric. If there is a marked rise in the agglutination titre the case is certainly one of enteric fever. Every case of true enteric fever should give a complete reaction in a dilution of 1:100 at some period of the disease. In the case sheets of many of the men sent here it is noted "Widal reaction 1:40." Now nearly all inoculated men will give a positive reaction in this dilution for months and in some cases for years after inoculation.

Again, in the 1910 report from the same depot we find the following:—

> In paratyphoid fever the Widal reaction is invariably raised for the *B. typhosus*, especially during the first week of fever, and may be just as high for this bacillus as that shown during an attack of ordinary enteric fever. The reaction for para A is as a rule lower and may only be present in such dilutions as 1:20 and 1:40, and possibly only a trace in the latter; it is also as a rule transient and may only be found for a few days in the later stages of the disease or early days of convalescence, and as a rule disappears in a few weeks, although in some cases we have found it a year after the fever. The group agglutinins for typhoid also disappear rapidly in contrast to the specific agglutinins after an attack of true typhoid fever, which remain raised for months and years in some cases. Thus we have the apparent anomaly of a man passing through a fairly severe attack of enteric fever (clinically) and giving a few weeks later an entirely negative reaction. This has happened here in several cases from whose blood the *B. para A* had been isolated and whose agglutination titre had (during the fever) been high for both typhoid and para A. In some cases also the paratyphoid reaction may entirely disappear, leaving a raised titre for *B. typhosus*, and again very rarely the titre for paratyphoid may remain raised without any agglutinins for *B. typhosus*.

An article published in the *Journal of the Royal Army Medical Corps* also points to the fact that army bacteriologists were quite alive to the importance of repeated Widal estimations in 1910. The paper referred to is "An Inquiry into a Small Epidemic of Paratyphoid Fever in a Camp in India," by Major H. W. Grattan, R.A.M.C., and Major D. Harvey, R.A.M.C.[1] In this epidemic all the men who contracted the fever were inoculated against *B. typhosus*, and it is interesting to note that the bacillus was recovered from the blood in every case but one. The charts of the agglutination curves were published and are here reproduced. (See Chart I.)

To take another example, Chart II. is from a paper published in the *Journal of the Royal Army Medical Corps*, 1911, xvii., showing agglutination curves in a case of

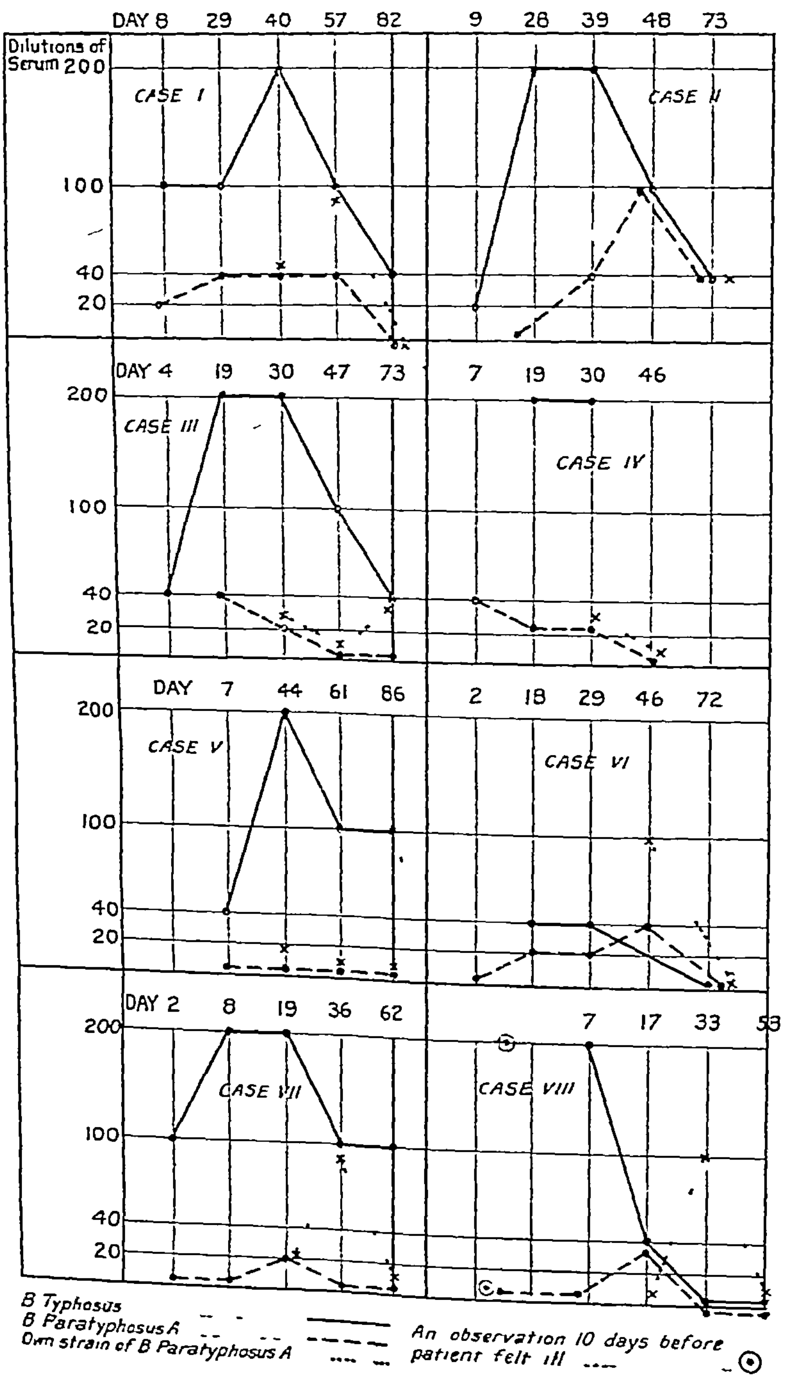
CHART I



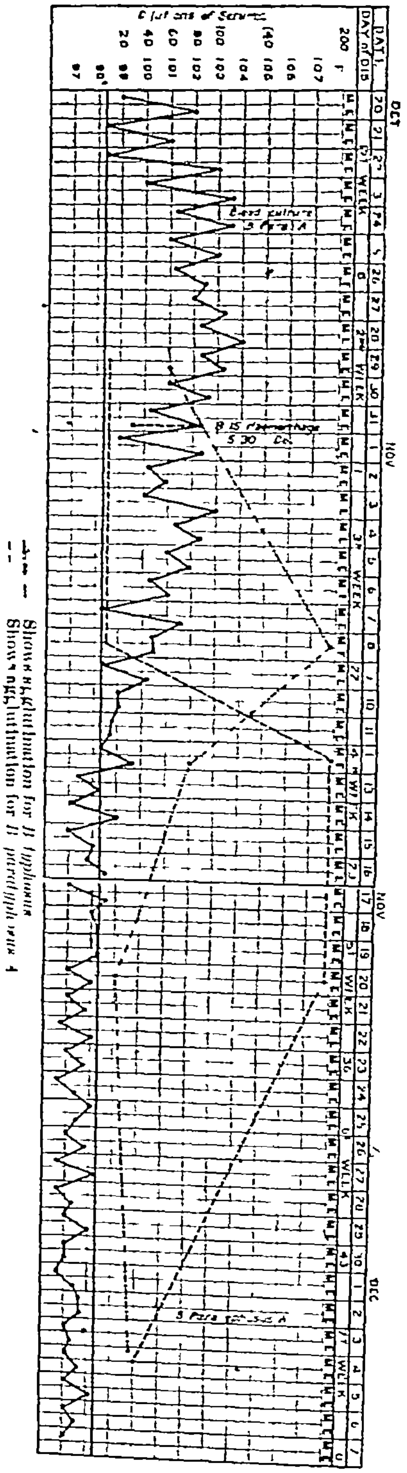


CHART II

paratyphoid A fever occurring in a man inoculated against *B typhosus*

This paper by Major H. W Grattan R A M C, and Captain J L Wood R A M C, gives an excellent account of the serum reactions of cases of paratyphoid A fever in inoculated men, and also mentions the frequency of the low titre of the serum for para. A. This point Professor Dreyer laid stress on at a meeting of The Royal Society of Medicine on Nov 9th 1915 His words at the meeting were —

> In every case bacteriologically proved to be a typhoid or paratyphoid B infection the agglutination method gave a positive diagnosis (i e 100 per cent of the cases), while in the case of paratyphoid A infection the agglutination test failed in only about 7 per cent of the cases Why are the results with paratyphoid A relatively so poor? The reason is that for a considerable time I did not know how low is the agglutination given by paratyphoid A in certain cases

This in the year 1915 and after he had been working with the two officers mentioned above, while all of the papers referred to in this communication were published before the end of 1911 The evidence brought forward will I think establish the fact that bacteriologists in the service were not quite so behindhand in the bacteriology of the enteric group of fevers as Drs Dreyer Ainley Walker and Gibson would lead us to believe

I am Sir, yours faithfully

H GRAEME GIBSON

THE NOMENCLATURE OF "INTERNAL SECRETION"

To the Editor of THE LANCET

SIR,—Dr Blair Bell, in his letter in your issue of Jan 6th, censures me for employing the term "endocrine organs" to denote organs of internal secretion I am however in no way responsible for this term as Dr Blair Bell seems to suppose although I think it convenient It has for some time been in general use, and appears to have come to stay Whether such a word as "endocrine" could be properly coined in Greek is beside the question What is certain is that it expresses what is wanted to be expressed—viz, the process of internal secretion by a simple word, which whatever it might be in Greek, is good enough English and has a familiar example in "endogen" to support it I am afraid many scientific terms used in medicine are not defensible on purely etymological grounds, yet quite well serve their purpose The term "endocrine" is at any rate hardly likely to be superseded by "endocritic" (which Dr Blair Bell has been in the habit of using) in its place, for apart from the fact that it is damned with very faint praise by the author of its being, who himself considers it "a poor word" it suggests to a physiologist the antithesis of "epicritic" which Head and Rivers have employed in a totally different connexion

As for the word "hormopoietic" which Dr Blair Bell now proposes we shall adopt in place of "endocritic" and regarding which he states that "the derivation is obvious and he thinks unassailable" a glance at a lexicon shows that this can only be derived from ὅρμος, a chain or cord so that the internally secreting organs thus become either "chain factories" or "rope walks" which as old Euclid used to say is absurd'

Regarding the term "hormone" I have given the history of this at length in my book on the "Endocrine Organs" published last year If Dr Blair Bell had looked at this or had consulted the original papers referred to in it he would have avoided more than one error Professor Starling who coined the word, and who as Dr Blair Bell says "is entitled to define his own term," has given a very precise definition of it[1]—viz "By the term 'hormone' I understand *any substance* normally produced by the body and carried by the blood stream to distant parts which it affects for the good of the organism as a whole He proceeds to give as examples of hormones, secretin, adrenalin *and carbonic acid*"[2] I myself propose to use the word "hormone" in the wide sense employed by its inventor, although Dr Blair Bell, following most authors, appears to wish to limit Professor Starling's definition to certain substances produced in definite organs

As long ago as 1894 it was shown by the late Dr George Oliver and myself that a specific organic substance is formed within the medulla of the suprarenal capsules which, when introduced into the blood, operates upon certain structures in the body in the same manner as drugs which are introduced from the outside, and as a matter of fact, this very substance which has been isolated, is now included in the Pharmacopœia amongst other drugs Since that time several other specific organic substances of like nature have been discovered although no other has as yet been chemically isolated Seeking for a convenient term to express such specific organic substances, whatever their action might be and realising my own classical shortcomings, I consulted with my friend and colleague, the late Professor W R Hardie, than whom, I suppose, our generation has seen no more accomplished classical scholar It was he who suggested the term "autacoid" (not autocoid, as Dr Blair Bell is made to put it, owing, I trust, to a printer's error), derived from ἄκος a remedy (whence also the term *panacea*, a universal remedy), and since this exactly expresses what is required—viz, a drug like substance formed by the body itself—I adopted the term defining an autacoid as a "specific organic substance formed by the cells of one organ and passed from them into the circulating fluid to produce effects upon other organs similar to those produced by drugs" But like other drugs autacoids either excite action or prevent action and for clarity's sake it is not only convenient but necessary to have two words expressive of these opposite effects To express excitation I adopted Professor Starling's term "hormone," which was already in general use, to express prevention the term "chalone" from χαλάω to make slack Thus the autacoids as well as other drugs, could be classed either as *hormonic* or *chalonic* according as they excite activity or prevent it To talk of provoking prevention, as Dr Blair Bell proposes to do, is a contradiction in terms

I may I hope be permitted to add without infringing the bounds set by modesty that I have at least as good a right as Dr Blair Bell to suggest an appropriate nomenclature for what is after all to some extent my own progeny

I am Sir yours faithfully,

University of Edinburgh Jan 9th 1917 F A. SCHAFER.

THE DIFFERENTIATION OF HEART MURMURS IN SOLDIERS

To the Editor of THE LANCET

SIR —The remarks of Professor David Drummond in THE LANCET of Nov 4th last regarding the influence of pressure upon the chest wall in altering the tone of cardiac murmurs suggest a comment upon the nature of such murmurs

A systolic apical murmur in the days when I was a medical student was looked upon as an indication of grave cardiac trouble We examined the heart carefully in cases of rheumatic fever and the appearance of a murmur was virtually considered to justify condemnation of the patient, so far as health was concerned for life Yet the question arose how if mitral regurgitation is occasioned by a deformity of the mitral valve which must take weeks or months to develop, can regurgitation be so quickly produced that a murmur may appear almost as soon as pain is complained of in the joints? Again it was soon noticed that not only a mitral systolic murmur but also a *pulmonary systolic murmur* was often present Then a paper by Dr Arthur Foxwell appeared attributing a pulmonary systolic murmur to dilatation of the right side of the heart Although Dr Foxwell's explanation may not have been correct in every detail it seemed to be reasonable and probably his main contention true—namely, that the murmur is associated with dilatation of the right ventricle chiefly in the neighbourhood of the conus arteriosus Accepting Dr Foxwell's explanation to be true, it was natural to conclude that if the pulmonary systolic murmur be due to dilatation of the right side of the heart, a mitral systolic murmur may also be due to dilatation of the left side of the heart This view was strengthened by noticing how frequently a systolic apical murmur arising during rheumatism may disappear and I wrote a short article in THE LANCET[1] which called forth a letter from Dr D B Lees, saying that he was intending to publish observations which supported the view of dilatation of the heart occurring in acute rheumatism

At that time it seemed reasonable to suppose—especially after meeting with definite cases of disease in the cardiac muscle in the post-mortem room, both in rheumatism and chorea—that the mitral systolic murmur was often due to dilatation of the heart allowing of mitral regurgitation Yet it became evident when looking up cases two to three years after a murmur had first been noted, that a mitral systolic murmur which had developed a harsh character before the patient first passed from under observation generally persisted, whereas a murmur described as lower pitched more often than not disappeared This gives rise to the question, What is the difference in causation of a low pitched and of a high pitched murmur? Can a systolic apical murmur be produced without the presence of regurgitation through the mitral orifice? Is it possible that the murmur may arise in the cardiac wall?

Professor David Drummond has recently commented upon the effect of pressure on the chest-wall upon cardiac murmurs laying stress on the fact that many murmurs can be abolished by pressure In my experience it is the low pitched murmurs which are very materially affected but I do not think are often completely abolished by pressure The lower tones disappear but a residuum of higher tones of more blowing character may remain We may assume that the higher pitched tones possibly indicate some temporary leakage through the mitral valve But how are the lower tones which disappear produced? In one detail I misread the letter of Professor Drummond when I recently ventured to add a note on my experience regarding the effect of pressure upon the chest-wall on murmurs Professor Drummond appears to consider that the murmurs which disappear are due to vibrations of the chest-wall. It is difficult quite to gather his meaning The chest-wall being the medium which, through the stethoscope, conveys murmurs to our ears must vibrate in all cases, but neither with functional nor organic disease can murmurs, it seems to me, originate in the chest-wall. If we abolish a murmur by pressure upon the chest-wall we presumably arrest the onward progress of those vibrations which compose the murmur In those murmurs which we do not abolish the vibrations are of a different nature, probably smaller and more rapid and pressure fails materially to influence them Earlier I have suggested whether it may be possible that a systolic murmur may arise in movements of the heart-wall In this connexion it may be interesting to remark that so frequently are slight functional murmurs audible both over the pulmonary and mitral areas in very young children that it seems to me they may be regarded as physiological In other words, cardiac action alters to some extent as age advances and some time may elapse before the cardiac sounds we are familiar with in adults become the fixed sounds of the heart. If we allow the view that some low-toned functional murmurs are produced by vibrations arising in unusual behaviour of the cardiac systole then perhaps we may consider some cases in which functional murmurs are heard to be a return to the comparatively unstable condition of early childhood.

---

[1] THE LANCET 1896, ii 170

Whatever view may be held with regard to the possibility of functional apical systolic murmurs arising in the wall of the heart, in cases where a diastolic sound is audible between the first and second sound we have definite evidence of some abnormal cardiac action. An additional shock to that of the impulse can often be felt by the hand, and when the heart is diseased and much hypertrophied the abnormal impulse may, in rare instances, give a tracing in which the wave it indicates, though more transitory, may equal the wave of the systole in height. We are, however speaking more particularly of hearts in which there is no disease In them, although it is not so easy to obtain a graphic record of abnormal cardiac action the same action is very commonly present It may persist for days or weeks or be present at one moment and absent at another The point, however, on which I wish to lay stress is that a diastolic sound occurring between the first and second sounds is associated with some abnormal cardiac action This action may be an exaggeration of a physiological action. The frequency of its presence in children supports such a view But the action, when present in a marked degree, is abnormal as far as the adult is concerned. The sound which appears in association with the abnormal action must also be regarded an abnormal but as a rule is of no serious import. Yet I have known it frequently to be mistaken by well qualified men for a presystolic murmur and the subject of it to be diagnosed as a sufferer from mitral stenosis The sound itself, however, need in no way be connected with valvular disease, and in most instances is merely an indication of some passing phase of cardiac action.

To sum up the foregoing remarks it may be said that so-called functional murmurs are, as a rule, lower in tone than those having an organic origin. They are more materially affected by pressure. Although in the case of apical murmurs some temporary leakage of the mitral valve may be present the question arises whether that portion of the murmur which can be readily abolished by pressure may not be due to vibrations associated with an abnormal cardiac systole In favour of this view is the fact that in association with a diastolic sound, occurring between the first and second sounds there is obviously an unusual action of the heart which in most instances, being transitory must be described as functional.

Since writing the above an observation I believe of Sir Wm. Broadbent has occurred to me which may be worthy of note at the present time when so many soldiers who have undergone severe physical exertion are under medical supervision Sir Wm Broadbent so far as I remember (I quote from memory) without referring to the theory of Dr Foxwell concerning the method of production of the pulmonary systolic murmur stated that he had met with cases in which healthy young men manifested pulmonary systolic murmur after prolonged physical exertion, such as mountain climbing It would be interesting if this observation should be confirmed It may be added also in connexion with the effect of pressure upon cardiac murmurs that I believe my attention was first drawn to the fact by a paper published by Dr Sydney Ringer and Dr A. G Phear many years ago Dr Moxon once said that the "art of originality is the art of forgetting" There may occasionally be experiences with which one becomes so familiar that one forgets whether they first impressed themselves upon one s mind in virtue of their own force or whether some other observer has drawn one's attention to them

I am, Sir, yours faithfully,

STAPHYLOCOCCUS MENINGITIS

To the Editor of THE LANCET

SIR,—The diagnosis of the case described as staphylococcus meningitis by Dr H. Bourges in your issue of Jan 6th (p 26) would appear likely to be at least doubtful Contamination by *Staphylococcus albus* in my experience in lumbar puncture, however carefully the skin is prepared is fairly frequent, both in cases where the meningococcus is found and where it is not found. Gram positive cocci in any turpentine abscess of some duration would not be uncommon. Authorities agree that many cases of cerebro-spinal fever occur where the causative organism which is very elusive is not found. The description of the case and the fact that the patient recovered makes it likely to be one of cerebro-spinal fever rather than one of staphylococcus meningitis

In reference to this contamination you published a few issues back the description of a puncture needle specially designed to obviate its contamination by the operator's fingers I find a simpler method is to flame the head of the needle after puncture and before withdrawing the stilette to collect the fluid.—I am, Sir, yours faithfully,

SHEFFIELD NEAVE
Temporary Captain, R.A.M.C

A NEW CULTURE MEDIUM FOR THE MENINGOCOCCUS

To the Editor of THE LANCET

SIR,—In a recent investigation into the anti coagulating action of acid aniline dyes on proteins, Holland[1] found that blood serum could be heated to high temperatures with these dyes without undergoing coagulation He stated that blood serum to which was added half its volume of a 2 per cent solution of Congo red, set to a clear jelly after sterilisation at 120° C and could be used as a culture medium for bacteria. This fact appeared to the writer who had been doing much culture work with the meningococcus, to offer an easily prepared medium upon which that organism could be grown readily, and which could be used for plate cultures. Accordingly, sloped tubes of the Congo red serum were prepared in the inspissator, and it was found that the medium was transparent, at any rate in the upper portion of the slope, although in the lower portion the colour was somewhat too dense to be accurately described as absolutely transparent. The top thin part of the slope was inclined to become hard. Stroke cultures of meningococcus on the new medium grew well and discrete red colonies were plainly visible in the upper part of the stroke when examined with a lens through the medium. The viability of the organism in these cultures was quite good, subcultures being obtained after two to three weeks The cultures also yielded the characteristic sugar reactions of the organism

Plates of the new medium were prepared by pouring the liquid mixture into the plate and sterilising at 120° C for 20 minutes There being a considerable amount of expressed water it was found inadvisable to use the inverted position for drying off the plates The surface of the medium was somewhat soft but it was quite transparent and colonies could readily be examined under the microscope. An opportunity has not yet arisen for using these plates for obtaining

tones which disappear produced? In one detail I misread the letter of Professor Drummond when I recently ventured to add a note on my experience regarding the effect of pressure upon the chest-wall on murmurs Professor Drummond appears to consider that the murmurs which disappear are due to vibrations of the chest-wall It is difficult quite to gather his meaning The chest-wall being the medium which through the stethoscope, conveys murmurs to our ears must vibrate in all cases, but neither with functional nor organic disease can murmurs, it seems to me, originate in the chest-wall. If we abolish a murmur by pressure upon the chest-wall we presumably arrest the onward progress of those vibrations which compose the murmur In those murmurs which we do not abolish the vibrations are of a different nature, probably smaller and more rapid, and pressure fails materially to influence them Earlier I have suggested whether it may be possible that a systolic murmur may arise in movements of the heart-wall In this connexion it may be interesting to remark that so frequently are slight functional murmurs audible both over the pulmonary and mitral areas in very young children that it seems to me they may be regarded as physiological In other words, cardiac action alters to some extent as age advances and some time may elapse before the cardiac sounds we are familiar with in adults become the fixed sounds of the heart. If we allow the view that some low-toned functional murmurs are produced by vibrations arising in unusual behaviour of the cardiac systole then perhaps we may consider some cases in which functional murmurs are heard to be a return to the comparatively unstable condition of early childhood.

Whatever view may be held with regard to the possibility of functional apical systolic murmurs arising in the wall of the heart in cases where a diastolic sound is audible between the first and second sound we have definite evidence of some abnormal cardiac action An additional shock to that of the impulse can often be felt by the hand and when the heart is diseased and much hypertrophied the abnormal impulse may, in rare instances, give a tracing in which the wave it indicates, though more transitory, may equal the wave of the systole in height We are, however, speaking more particularly of hearts in which there is no disease In them, although it is not so easy to obtain a graphic record of abnormal cardiac action the same action is very commonly present It may persist for days or weeks or be present at one moment and absent at another The point, however, on which I wish to lay stress is that a diastolic sound occurring between the first and second sounds is associated with some abnormal cardiac action This action may be an exaggeration of a physiological action The frequency of its presence in children supports such a view But the action, when present in a marked degree is abnormal as far as the adult is concerned The sound which appears in association with the abnormal action must also be regarded an abnormal, but as a rule is of no serious import. Yet I have known it frequently to be mistaken by well qualified men for a pre-systolic murmur, and the subject of it to be diagnosed as a sufferer from mitral stenosis The sound itself, however, need in no way be connected with valvular disease, and in most instances is merely an indication of some passing phase of cardiac action

To sum up the foregoing remarks it may be said that so-called functional murmurs are as a rule, lower in tone than those having an organic origin They are more materially affected by pressure Although in the case of apical murmurs some temporary leakage of the mitral valve may be present the question arises whether that portion of the murmur which can be readily abolished by pressure may not be due to vibrations associated with an abnormal cardiac systole In favour of this view is the fact that in association with a diastolic sound, occurring between the first and second sounds there is obviously an unusual action of the heart which in most instances, being transitory, must be described as functional

Since writing the above an observation, I believe of Sir Wm. Broadbent has occurred to me which may be worthy of note at the present time when so many soldiers who have undergone severe physical exertion are under medical supervision Sir Wm. Broadbent so far as I remember (I quote from memory), without referring to the theory of Dr Foxwell concerning the method of production of the pulmonary systolic murmur, stated that he had met with cases in which healthy young men manifested pulmonary systolic murmur after prolonged physical exertion, such as mountain climbing It would be interesting if this observation should be confirmed It may be added also in connexion with the effect of pressure upon cardiac murmurs that I believe my attention was first drawn to the fact by a paper published by Dr Sydney Ringer and Dr A G Phear many years ago Dr Moxon once said that the "art of originality is the art of forgetting" There may occasionally be experiences with which one becomes so familiar that one forgets whether they first impressed themselves upon one's mind in virtue of their own force or whether some other observer has drawn one's attention to them

I am, Sir, yours faithfully,

Jan. 8th 1917 THEODORE FISHER, M D Lond

STAPHYLOCOCCUS MENINGITIS

To the Editor of THE LANCET

SIR —The diagnosis of the case described as staphylococcus meningitis by Dr H Bourges in your issue of Jan 6th (p 26) would appear likely to be at least doubtful Contamination by *Staphylococcus albus* in my experience in lumbar puncture, however carefully the skin is prepared is fairly frequent, both in cases where the meningococcus is found and where it is not found. Gram positive cocci in any turpentine abscess of some duration would not be uncommon Authorities agree that many cases of cerebro-spinal fever occur where the causative organism which is very elusive is not found. The description of the case and the fact that the patient recovered makes it likely to be one of cerebro-spinal fever rather than one of staphylococcus meningitis

In reference to this contamination you published a few issues back the description of a puncture needle specially designed to obviate its contamination by the operator's fingers I find a simpler method is to flame the head of the needle after puncture and before withdrawing the stilette to collect the fluid.—I am, Sir, yours faithfully,

SHEFFIELD NEAVE
Temporary Captain R.A.M C
Military Laboratory for Cerebro-spinal Fever Ipswich

A NEW CULTURE MEDIUM FOR THE MENINGOCOCCUS

To the Editor of THE LANCET

SIR,—In a recent investigation into the anti coagulating action of acid aniline dyes on proteins, Holland[1] found that blood serum could be heated to high temperatures with these dyes without undergoing coagulation He stated that blood serum, to which was added half its volume of a 2 per cent solution of Congo red, set to a clear jelly after sterilisation at 120° C and could be used as a culture medium for bacteria This fact appeared to the writer, who had been doing much culture work with the meningococcus, to offer an easily prepared medium upon which that organism could be grown readily, and which could be used for plate cultures. Accordingly, sloped tubes of the Congo red serum were prepared in the inspissator, and it was found that the medium was transparent, at any rate, in the upper portion of the slope, although in the lower portion the colour was somewhat too dense to be accurately described as absolutely transparent The top thin part of the slope was inclined to become hard. Stroke cultures of meningococcus on the new medium grew well, and discrete red colonies were plainly visible in the upper part of the stroke when examined with a lens through the medium. The viability of the organism in these cultures was quite good, subcultures being obtained after two to three weeks The cultures also yielded the characteristic sugar reactions of the organism

Plates of the new medium were prepared by pouring the liquid mixture into the plate and sterilising at 120° C for 20 minutes There being a considerable amount of expressed water it was found inadvisable to use the inverted position for drying off the plates The surface of the medium was somewhat soft, but it was quite transparent, and colonies could readily be examined under the microscope. An opportunity has not yet arisen for using these plates for obtaining

INDIAN MEDICAL SERVICE

Manifold Col C C C B

THE EMPLOYMENT OF AMERICAN DOCTORS

Publicity has recently been given in the daily press to the statement that young American doctors have volunteered their services and will be freely substituted for British doctors in the hospitals of this country in order to set free the present medical officers of military age for active service abroad A recent statement in an American journal that the Director General of our Army Medical Service had asked for the supply of a hundred or more young American doctors has we believe not been contradicted and may therefore be taken as the policy of the Army Medical Department To them will be allotted posts in military hospitals in this country which they can fill without possessing either a commission or a qualification registrable here A corresponding number of British doctors of military age holding commissions will thus be set free. So far then as military occupation goes the accounts in the daily press have been based upon fact if misleading in detail As regards civilian practice, as far as we know the question of the employment of American doctors has not arisen in any practical form The legal obligations of the civilian practitioner both in hospital and private practice, prevent the employment here of those whose names do not appear on the British Medical Register So long as the present absence of reciprocity between the United States and this country in medical matters remains unrectified registration implies the obtaining in this country of a medical diploma recognised by the General Medical Council

---

NEW RED CROSS HOSPITAL FOR GLOUCESTER—The Bishop of Gloucester's Palace at Gloucester has been fitted up as a Red Cross hospital It will accommodate 100 patients, contains an X ray apparatus and a complete electrical massage installation

April, 1915, in charge of a clearing station, came home three months later with severe shell shock, and was invalided out of the service in October, 1915 In spite of his poor health he then took over the practice at Earby of his brother, the late Surgeon P D Pickles who died of gas poisoning after going down with H M S *Russell* in the Mediterranean last year Unfortunately, his health did not improve and an attack of broncho pneumonia following influenza proved fatal

Captain C C Pickles s service to his country was undertaken with no thought of himself His transference from combatant to medical service was made at a time when doctors were urgently required for the Army, and the strain of his work contributed to the illness from which he never quite recovered His record and that of his family are a notable achievement Captain Pickles married in June of last year Dorothy B E Wilkinson, only daughter of Charles Wilkinson, of Boston Spa and Leeds

THE FIRST BRITISH RED CROSS UNIT IN ITALY

We have received from Dr G S Brock chief medical officer to the unit a report of the first year s hospital work drawn up for the Joint War Committee from which we take the following —

Villa Trento, the headquarters of the ambulance unit, is on the high road beyond the bridge over the river Natisone at Manzanol, and within a dozen miles of the fighting on the Isonzo front, on Monte Sabotino, at Oslavia, and on Monte Podgora The villa is a large building of seventeenth century design, belonging to the Conte di Trento, with a central portion of three storeys and wings of two storeys, flanked on either side by tall pine trees Behind the latter, on one hand, is a line of offices occupied by a detachment of Carabinieri, while on the other is a long building of which the upper storey, ordinarily used as a granary, now forms an important part of the hospital There is plenty of garden space where convalescents can take air and exercise enjoyably

Dr Brock tells us that at the time of the unit's arrival (Sept 5th 1915) the villa was occupied as an Italian hospital and the first ambulance work consisted in transporting some 50 patients to the neighbouring Abbazia Hospital Much had then to be done both in improving the very bad sanitary conditions and in adapting the villa to its purpose This work, performed almost entirely by members of the unit, was speedily carried out On Sept 12th was received the first batch of 8 patients, and by the end of the month the number accommodated was 55 After dealing with defective sanitation the unit turned its attention to getting a satisfactory water supply Water from a deep well was found by Captain Franchini of the VI Army Corps, to be quite free from pathogenic organisms A second source from an open stream in spite of filtering was impure but no doubt often found its way into the unit s food and drink Fortunately another source became available from the Acquedotto Poiano by the kind help of Colonel Moreno of the "Genio ' of the Army Corps, to which the unit is attached This water is of excellent quality and practically unvarying quantity is moderately soft and under high pressure The effect of this new water supply on the health of the unit was immediate there being no longer cases of diarrhœa. The absence of heating arrangements did not lead to serious inconvenience during the summer, but on the approach of cold weather something had to be done The Genio provided stoves for all the wards and also for some of the rooms By means of these and a number of petroleum stoves the villa has been fairly well heated The villa is lighted by its own electric installation of gas engine accumulators The laundry arrangements were totally inadequate Application was made to General Cavicchia of the Direzione di Sanità of the 2nd Army, laying before him a scheme for the erection of a disinfecting room, washhouse ironing room, and drying room which he very kindly had carried out by the Genio, and also provided a steam disinfector and a complete set of apparatus consisting of two large galvanised iron boilers a soaking tank and a rinsing machine Regarding the disposal of refuse all combustible materials are burnt by two incinerators—one of brick built by the unit the other of iron supplied by the Direzione di Sanità Non combustible materials are buried in a neighbouring field

The original idea in the minds of the organisers of the ambulance unit, Dr Brock tells us, was to provide as an adjunct to it a small evacuation hospital of 25 beds with 25 stretchers for cases requiring to remain in the hospital for a few hours only The accommodation, however, has been gradually so greatly extended that 97 patients can now be provided with beds, and there is room in an emergency for more The unit's funds do not at present allow of filling more than about 65 of these, and this may be considered for the moment the normal number The ground floor of the villa was appropriated, as far as possible, for hospital purposes The outbreak of Asiatic cholera made it necessary to prepare an isolation ward A part of the granary was partitioned off into two rooms, one for suspected cases and the other for cases such as typhus or cholera After the great battle in the first week of November, 1915, a great rush of wounded came from the Gorizia section All the beds (54) in the villa were quickly filled and the remainder of the patients were put on mattresses or on straw in the granary in four long lines As many as 150 patients were at one time in the hospital The remaining part of the granary has since been partitioned off and divided into two, so as to form two large wards

An out-patient department has also become a necessity Many soldiers sent from the front into reserve are encamped in this neighbourhood often unaccompanied by a medical officer In case of illness they usually come for advice to this hospital The number of these soon necessitated an out-patient department A waiting room and consulting-room have been partitioned off in the granary, and this work is undertaken by an Italian colleague, Lieutenant De Lisi, who has been attached to the unit from the first and has rendered invaluable assistance

The pharmacy of the hospital is under the care of Lieutenant Balotta, another Italian officer detailed by the Direzione di Sanità to assist the unit A certain amount of the drugs used has come from England, but the greater part of the pharmacy supplies is obtained from the "Magazzino Avanzato' of Udine, These are used not only for the hospital, but also for the out-patients A certain equipment (hospital supplies other than drugs) was brought out from England and more followed later by sea But a great many things had to be obtained locally, as, for instance, the furniture of the operating room Fortunately a large number of bales containing such stores, collected by the Ladies' Committee in England and Scotland, were sent with members of the unit coming out in time for the great rush of wounded Since then the hospital has received many generous contributions of money and supplies from friends in Britain and from British residents in Italy Large consignments have been received from various war hospital supply depôts including those of Kensington Belgravia, Norwich, and Rome and a very large one has now arrived from the Scottish Red Cross

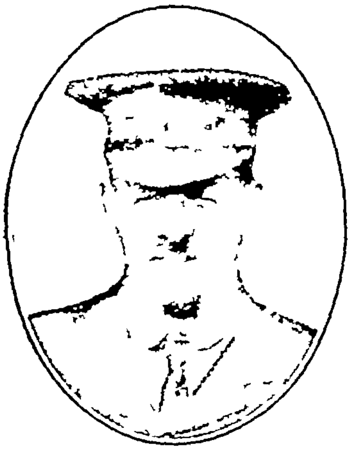
When the hospital was opened in September, 1915, the unit expected to act only as a clearing station Later, according to instructions received from Colonel Moreno in regard to the stay of wounded in the hospital, the unit was to work only as a field hospital It was soon realised, however, that when little fighting was in progress the work done might be that of a small base hospital, but when a rush of wounded is anticipated all the sick and wounded who can be safely transported are evacuated in order once more to take on the role of a field hospital

The medical staff consists of the chief medical officer, who is also its "direttore" and two surgeons The present chief medical officer has been with the unit since its work began The two surgeons, Dr W E Thompson, and Dr W A Propert joined later—in October 1915—when Dr W R Dakin and Professor Henry Tonks, F R C S, the well-known artist, who had come out with the unit were obliged to leave by other engagements Mr R Creasy, of Windlesham Surrey, took duty for a month at the beginning of 1916 in the absence of one of the surgeons Dr Propert rejoined some time ago As to nursing, the unit at first went on as best it could with the help of men belonging to the unit and of some Italian soldier orderlies Nineteen of the members seven of them medical students took duty as nurses and dressers Eventually the authorities consented to female nurses being employed The advent of female nurses made a vast difference for the better many of them speaking Italian Of our male nurses and dressers only five remain on the hospital side.

OBITUARY OF THE WAR

NORMAN ERNEST JASPER HARDING, M B, Ch B Edin,

MAJOR ROYAL ARMY MEDICAL CORPS



Major N E J Harding who died of cholera at Colaba Military Hospital on August 10th last while in command of a stationary hospital at Bombay, was 41 years of age He studied at Edinburgh and at University College, Liverpool graduating in medicine at Edinburgh University in 1900 and entering the Royal Army Medical Corps a year later after taking a diploma in Public Health He obtained his captaincy in 1906 and his majority in 1914 He was seriously wounded in the Boer War, and for his services at that time was decorated with the Queen's medal with two clasps and the King's medal. He went to France with No 12 General Hospital on the outbreak of war and served there for 15 months, before taking to India the unit which he was commanding at the time of his death Previously to the outbreak of war he had served in Burma and on the West Coast of Africa He contributed an article on the Value of Koch's Treatment of Malaria, to the *Journal of the Royal Army Medical Corps* and other articles of a historical and professional character

In 1908 Major Harding married Dorothy, oldest daughter of the late Ernest Wetton, of Maidstone, and of Kobe, Japan

ROGER FORREST HUGHES, B A M B, Ch.M Sydney,

CAPTAIN AUSTRALIAN ARMY MEDICAL CORPS

Captain R F Hughes who was killed on active service on Dec 11th last was 26 years of age and the elder son of Sir Thomas Hughes who was for many years Lord Mayor of Sydney He was educated at St Ignatius College Sydney, entering the Sydney University where he first graduated in arts, and obtained his medical qualifications at the end of 1915 He then filled the position of resident medical officer at St Vincent's Hospital until March, 1916, when he enlisted in the Australian Army Medical Corps After serving for six months at a base military hospital in Sydney he was detailed for service as regimental medical officer to an Australian battalion in France arriving there early in December Ten days later while dressing a wounded man in his advanced station he was severely wounded and died the same day Captain Hughes was well known in athletic circles in Sydney He represented his school at cricket and football and his university at hockey Just prior to leaving Australia he married Eileen, youngest daughter of M E Maher of Collaroy Station, Merriwa, N S W with whom and his parents much sympathy will be felt for his untimely death at the outset of a promising career

CHARLES KENNETH McKERROW, M A M B B C Camb,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain C K McKerrow, who died of wounds received the same day on Dec. 20th last, at the age of 33 was elder son of the late Dr George McKerrow, of Ayr He was educated at Cargilfield and Charterhouse Schools gaining from the latter the Science Scholarship of his year for Cambridge and later an open scholarship at Clare College He took a first class in science graduated M B and B C in 1908, obtaining in the same year the diploma of the Conjoint Board After holding resident posts at St. George's Hospital and being extern to the 1st Frauenklinik in Vienna he joined his father in practice in Ayr for some years On obtaining a commission in the R.A.M C in June 1915, he was appointed regimental medical officer to a battalion of Northumberland Fusiliers, going with them to France where he remained until his death

Captain McKerrow was not one sided in his development At school and later he had some reputation as a middle weight boxer and he also played Association football for his college His superior officer writes of him "A few days before his death Captain McKerrow read an excellent paper on Trench Fever before our Divisional Medical Society, giving proof of his careful clinical work even in the trenches I formed a very high opinion of him both as a gallant soldier and a skilful surgeon He was absolutely fearless in the performance of his duty

In January 1915 Captain McKerrow married Jean only daughter of the late James Craik, and leaves a widow and one son

CLIFFORD CRAWSHAW PICKLES, M R C S Eng D P H Leeds

LATE CAPTAIN ROYAL ARMY MEDICAL CORPS (T F)

Mr C C Pickles who died on Dec 22nd last, after being invalided out of the Royal Army Medical Corps was 30 years of age, and the third son of Dr J J Pickles, of Camp road Leeds, of whose six sons five were members of the medical profession and one a student before the war Educated at the Leeds Grammar School Clifford Pickles entered the School of Medicine at the University of Leeds obtaining in 1909 the Conjoint Board qualification, and two years later the Public Health diploma of his University After holding resident appointments at Leeds and acting as assistant in general practice at Harrogate and Ossett he was appointed medical inspector of school children under the North Riding Education Committee and was stationed at Malton, where he was also in charge of the local company of the 5th Yorkshire Territorials At the outbreak of hostilities he was medical officer at Gateforth Sanatorium near Selby, and on mobilisation served with the 5th Yorkshire Regiment at home for some months, after which he was transferred to the medical service as a captain He went out to France in

Obituary.

THE SENATOR DE GIOVANNI

OUR Rome correspondent writes —After Grocco, Baccelli, and, after Baccelli De Giovanni the Tuscan the Roman, and now the Venetian schools respectively have, in the year just closing lost their most brilliant medical ornaments.

Born near Mantua on Sept. 27th, 1837 Achille De Giovanni began his medical studies in his native Lombardy, but like so many of his compatriots, had to suspend them on the outbreak of the war against Austria Serving under Garibaldi, whose commendation he earned in the fighting line, he re entered the classes in 1860 the year of Lombardy's liberation, and threw himself into their work with an ardour which carried him with distinction through the curriculum till his graduation, with honours in the final school More than one University thereafter solicited and gained his services on its clinical staff, Pavia, Naples, and Padua especially, but in the last-named he found such acceptance that he never left it and became from year to year the most popular and effective teacher on its medical professoriate A consultant in much request throughout the kingdom, he was also a conspicuous figure at the medical congresses held annually in the leading cities, contributing to the transactions and debates papers on auscultation and percussion, on gout, on 'dry arthritis," and on the pathology of the vena cava inferior, to enumerate some of his best known work But in his later years State medicine became his absorbing interest particularly in the field of tuberculosis, where he followed up a series of elaborate clinical investigations by others of a purely prophylactic tenor, till he was recognised as the inspiring spirit and indeed as the initiator, of the "Lega Internazionale contro la Tubercolosi" His professional distinction and his public spirit won for him admission into the Senate of the kingdom, where he made his knowledge and his sagacity felt in many a debate on hygienic legislation In private life he was austere even to stoicism, while essentially kind of heart and gracious in manner and address His death, in its dramatic suddenness, was quite in keeping with the tenor of his life. He had opened the Medicus Annus of the Paduan school by a brilliant address on Monday Dec. 4th, when, next day, he fell ill with cardiac symptoms supervening on the rheumatism to which he had long been a martyr, and in four days he succumbed. In both Houses of Parliament his death was put on record as a "national loss," while his *Alma Mater*, of which he had for four years been Rector Magnificus suspended its functions with the flag of Italy half mast high

Up to the end of March, 1916, the numbers of patients treated were as follows —

Consultations in out-patient department	1422
Total admitted to hospital up to March 31st	1022
discharged ,, ,,	957
In hospital on April 1st	55
Average number of days in hospital per patient	9·8
Total number of deaths	27
Deaths per cent of patients admitted	2·6
,, ,, among sick only	0·1
,, ,, wounded only	4·5

The death rate was thus very low considering the many severe cases. The only death among medical cases was in a case of double pneumonia. The 398 sick discharged were nearly all cured or convalescent. Among the few exceptions were eight cases of cholera removed to cholera hospitals on diagnosis, four terminating fatally. Cases of frozen feet with the skin apparently uninjured have been counted as medical, but those with the skin blistered or broken as surgical. The nature of the medical cases chiefly met with will be seen from the following table, relating to 459 sick admitted up to the end of March, 1916

Disease	Percentage to total sick	Months of prevalence
Frozen feet	14·0	December January and February
Gastro-enteritis (including gastritis and enteritis)	13·5	All months but especially December and March
Fevers of influenzal type trench fever	12·0	December and March
Rheumatism chronic and muscular	9·0	All months
Bronchitis	7·0	From November onwards
Jaundice	6·0	January February and March
Paratyphoid	3·8	From November onward
Pleurisy	2·9	From December onwards
Otitis media	2·0	
Conjunctivitis	2·0	February and March
Cholera	1·8	Nov 9th to Dec 7th
Pneumonia	1·6	December January and February

It is remarkable that no case of cholera occurred in members of the unit, many of whom were constantly coming in contact with cholera patients; this was no doubt the result of the precautions taken, including anti cholera vaccinations of nearly all the members shortly after arrival with vaccine supplied by the Lister Institute of London. It is also striking to find true typhoid absent, as well as the comparatively large number (17) of paratyphoid cases. In the Italian Army antityphoid vaccination has been practised, but not antiparatyphoid vaccination. A combined vaccine is, however, now being largely used containing 800 million typhoid and 500 million paratyphoid B bacilli per cubic centimetre, in three doses at intervals of a week the last two doses of 1 c c being double the first. The paratyphoid was on the whole of a benign type and unaccompanied by grave complications. A great difference of opinion prevails as to the causation of "piedi congelati" (frozen feet). Dr Brock is convinced that the puttee is the chief offender.

There have been a great many visitors, both Italian and English. The King of Italy has paid three visits, at the last one decorating the commandant, Mr G M Trevelyan, with the silver medal for valour. Another royal visitor on three occasions was the Duchess of Aosta.

A report follows on the surgical cases in the hospital by Mr W E Thompson, M B, Ch B Edin. The numbers of surgical cases he tells us, greatly varied. At the commencement wards had been prepared and an operating theatre reconstructed. Instruments in large variety, tables and cupboards of good sterilisable material were procured and a good supply of dressings was put ready to hand. It was soon found that more apparatus was needed especially a bacteriological laboratory and an X ray installation. Both of these have since been sent the microscope the gift of Miss Gray, of Rome. The other gift the X ray installation, is largely owing to the generosity of Dr Barbour, of Edinburgh, and Mr Saunders, of Croydon. A great variety of surgical cases has been dealt with from cuts and bruises to severe head chest and abdominal injuries. Up to March 31st 1916 there were 84 operations, 34 of these being major. Taking into account the severity of so many cases where the only object attainable was relief of suffering, the death rate of operation cases was just over 10 per cent and the total mortality of all surgical cases about 1 5 per cent. There were 21 amputations of the leg and arm—12 being of the leg. Four cases of traumatic empyema were operated on, in one a piece of shrapnel being literally picked off the back of the heart. Practically every surgical case required drainage in some form, and some for a length of time. For gas gangrene nothing was found better than peroxide of hydrogen and eusol, followed by 5 per cent saline. The best absorbent dressing for these cases was the sphagnum moss bags presented by Mr C W Cathcart, of Edinburgh, and others. These were a great saving in dressings as well as an ideal dressing.

Two supplementary reports bring the figures up to the end of June and August respectively, and deal with the second year of work. During the three months April to June the total patients admitted increased from 1022 to 1492—792 sick, 700 wounded. Unfortunately on June 7th the unit lost Dr Propert's services by his enforced return to England. For the month of August the admissions to hospital reached a high figure, especially in the early part during the great Italian offensive which resulted in the capture of Gorizia, when there was a daily average of 160 occupied beds. As may be easily imagined, the strain on organisation and personnel was very severe, since not only were the numbers sometimes double that for which the unit is normally equipped, but it had to play the rôle of a clearing hospital as well. Fortunately a great many wounds were light, many patients in a day or two being fit to return to their regiments. Great although the strain was, everything went on with wonderful smoothness and efficiency, calling forth praise both from the Italian military and sanitary authorities and from the Chief Commissioner of the British Red Cross for the Mediterranean, Sir Courtauld Thompson, who happened to be here during the most strenuous part of it.

THE PANEL COMMITTEE FOR THE COUNTY OF LONDON AND THE MOBILISATION OF THE MEDICAL PROFESSION

The following resolutions were passed by the Panel Committee of the County of London at their meeting on Tuesday last Jan 9th —

(a) That the Panel Committee are of opinion that, in respect to the proposal to mobilise the medical profession, it is essential in order to secure the efficient working of any scheme adopted that extended powers be conferred upon the Central Medical War Committee in connexion therewith and that the personnel of the Committee be strengthened by the addition of at least six practitioners actively engaged in panel practice one of whom should be a woman.

(b) That the Panel Committee are of opinion that, in so far as the recommendations of the Central Medical War Committee shall have reference to the services rendered by the medical profession to the civil population if accepted these should be carried into effect by a small executive committee appointed from the members of the Central Medical War Committee with lay members appointed by the Director of National Service.

(c) That the Panel Committee are of opinion that the difficulties of the Committees in this connexion would be greatly lessened and a considerably increased number of medical men set free for active service abroad without serious interference with the medical needs of the civilian population if much greater use were in future made of the part time services of civilian doctors for the treatment of sick and wounded soldiers whilst in hospitals and for other military duties in this country.

(d) That copies of the foregoing resolutions be forwarded to the Central Medical War Committee the Director of National Service, and to the other Government Departments concerned.

We comment on these resolutions elsewhere.

CONVALESCENT HOME IN *CALCUTTA*.—An offer has been made and accepted from Calcutta to entertain 100 men and 10 or more officers invalided from Mesopotamia. Mr Galstaun has given the use of his house in Circular road while Raja Kristo Das Law has lent No 23 Theatre road as a residential club for convalescent officers. The Calcutta nursing division of the St John Ambulance Brigade are fitting out these two fine residences for the purposes they are to serve. The estimated cost of the furnishing and upkeep for five months has been put at 1½ lakhs of rupees, and this amount is likely to be forthcoming.

METROPOLITAN ASYLUMS BOARD THREATENED SHORTAGE OF AMBULANCES.—The lack of motor and driver mechanics is reducing the ambulance service of the Asylums Board to a dangerous extent. The Ambulance Committee states that 37 per cent of the ambulances are awaiting repair, and that probably within a few months the ambulance service will be unable to remove fever patients from their homes. The committee urges on the Board the necessity for the return of mechanics who have been taken for Army or munitions service.

Obituary.

THE SENATOR DE GIOVANNI

OUR Rome correspondent writes —After Grocco, Baccelli, and after Baccelli De Giovanni the Tuscan the Roman, and now the Venetian schools respectively have, in the year just closing, lost their most brilliant medical ornaments.

Born near Mantua on Sept. 27th, 1837 Achille De Giovanni began his medical studies in his native Lombardy, but like so many of his compatriots, had to suspend them on the outbreak of the war against Austria Serving under Garibaldi, whose commendation he earned in the fighting line, he re entered the classes in 1860 the year of Lombardy's liberation, and threw himself into their work with an ardour which carried him with distinction through the curriculum till his graduation, with honours in the final school. More than one University thereafter solicited and gained his services on its clinical staff, Pavia Naples, and Padua especially, but in the last-named he found such acceptance that he never left it and became from year to year the most popular and effective teacher on its medical professoriate A consultant in much request throughout the kingdom, he was also a conspicuous figure at the medical congresses held annually in the leading cities, contributing to the transactions and debates papers on auscultation and percussion, on gout on dry arthritis" and on the pathology of the vena cava inferior, to enumerate *some of* his best known work. But in his later years State medicine became his absorbing interest particularly in the field of tuberculosis, where he followed up a series of elaborate clinical investigations by others of a purely prophylactic tenor till he was recognised as the inspiring spirit and indeed as the initiator, of the "Lega Internazionale contro la Tubercolosi." His professional distinction and his public spirit won for him admission into the Senate of the kingdom where he made his knowledge and his sagacity felt in many a debate on hygienic legislation. In private life he was austere even to stoicism while essentially kind of heart and gracious in manner and address His death in its dramatic suddenness was quite in keeping with the tenor of his life. He had opened the Medicus Annus of the Paduan school by a brilliant address on Monday Dec. 4th when, next day, he fell ill with cardiac symptoms supervening on the rheumatism to which he had long been a martyr, and in four days he succumbed. In both Houses of Parliament his death was put on record as a "national loss,' while his *Alma Mater* of which he had for four years been Rector Magnificus suspended its functions with the flag of Italy half mast high

ROYAL COLLEGE OF SURGEONS OF ENGLAND —The second series of lectures on the Anatomy of the Human Body will be delivered by Professor Arthur Keith, Conservator of the Museum, for first-aid and ambulance students, at 5 P M, in the theatre of the College in Lincoln's Inn Fields, on Mondays Wednesdays, and Fridays, commencing on Monday next Jan 15th Anatomical preparations and specimens, used for purposes of illustration, will be placed on exhibition in the theatre from 3 to 5 P M on each lecture day On the following day the same preparations will be placed in the hall of the Museum, where they may be studied between the hours of 10 A.M and 5 P M

At the Preliminary Science Examination for the Licence in Dental Surgery the following candidates were approved in the undermentioned subjects —

Chemistry and Physics —Reginald James Hooker Municipal Technical College Brighton Elisha Clemens Keet, South African College Phillip Heygate Knowles Reading School George Levy Guy's Hospital Peter John Morrison South African College and Guy's Hospital and George Edward Smith Liverpool University

Chemistry —Levi Austin Bevan University of North Wales Bangor and Gilbert James Burbery Rowe, Municipal College, Bournemouth

Physics —Gerald Fraser Smith Middlesex Hospital

ROYAL MEDICAL BENEVOLENT FUND —At a meeting of the committee held on Dec 12th, 1916, 30 cases were considered, and £317 15s granted to 28 of the applicants The following is a summary of the cases relieved —

Widow aged 44 of M B Lond who practised in London and died in August, 1916 Owing to the war it was impossible to sell the practice Applicant lives in own house which is to be sold and when her affairs are settled her income will only be about £120 a year Has two children aged 8 and 9 Wants help towards the education of her son who is a candidate for Epsom but not likely to be elected for over a year Voted £5 —L R C P Edin married who practised at Bervie N B Owing to ill health his earnings have only been about £70 per annum for some time and his wife aged 70 is now blind and a daughter who was a housekeeper has had to give up her post so as to be able to nurse her father and mother Voted £24 in two instalments —Daughter aged 69 of M R C S Eng who practised at Cambridge and died in 1887 Applicant was able to earn a living by taking in paying guests on the south-east coast until the war commenced but since has not been successful and has had to give up her house Only income £35 per annum Relieved once, £12. Voted £12 in 12 instalments —Daughter aged 70 of M R C S Eng who practised in London and died in 1875 Applicant was a governess in Russia when the war commenced and all her savings were in a Berlin bank For the last two years has earned a living by clerical work but her eyesight has now failed and has had to give it up Only income a pension of £30 from another charity Relieved twice £24 Voted £12 in 12 instalments —Daughter aged 50 of M R C S Eng who practised in India and London and died in 1873 Applicant left unprovided for and owing to ill health unable to earn a living Only income £22 per annum Relieved three times £20 Voted £10 in two instalments —Daughter aged 58 of M R C S Eng who practised at Hammersmith and died in 1908 Owing to ill health unable to work and only income occasional help from friends and from the Guild Relieved nine times £122 Voted £18 in 12 instalments —Widow aged 59 of L S A. Lond who practised at Bournemouth and died in 1913 Has endeavoured to earn a living by taking in lodgers but since the war has been unsuccessful and has only received £3 this year Has received a gift of £26 from another society Relieved twice £24 Voted £12 in 12 instalments —Daughter aged 54 of M R C S Eng who practised in London and died in 1881 Left without means and very delicate and her small income has had to be expended on medical attention Income £25 from another society Relieved seven times £74 Voted £10 in two instalments —Daughter aged 51, of M R C S Eng who practised at Gillingham and died in 1914 Applicant left without means her father having been an annuitant of the Fund for some years Never trained to work and can only earn a few shillings a week in a domestic capacity Relieved three times £29 Voted £12 in 12 instalments —Widow, aged 74 of M R C S Eng who practised at Rye and died in 1891 Applicant's income is not more than £50 per annum and she has cataract in both eyes Her two daughters are married and unable to help her Relieved once £12. Voted £12 in 12 instalments —Widow, aged 65, of M R C S Eng who practised at Yelverton and died in 1908 Left without means and endeavours to make a living by taking in boarders but is not successful Her eyesight is bad. Relieved ten times, £119 Voted £12 in 12 instalments —Daughters aged 44 51 and 55 of M.R C S Eng who practised at Bodmin and died in 1912. On the death of the father the life interest in an estate ceased and the only certain income of the applicants is £5 each Two suffer from bad sight and the other quite unable to work. Relieved once, £18 Voted £18 in 12 instalments jointly —Daughter aged 70 of M D Lond who practised at Cheltenham and died in 1879 Applicant was left without means and has always had bad health and is now suffering from acute rheumatism. Only income £39 per year from another charity and a small annuity Relieved three times, £36. Voted £12 in 12 instalments —Widow aged 43 of M R C S Eng who practised in North Wales and died in 1910 Applicant was left without means and had two young children now aged 10 and 7 years Lives with her aged parents who are not well off and can only provide a home Relieved five times £50 Voted £10 in two instalments.—Widow aged 75 of L.S A Lond who practised in Bermondsey and died in 1887 Applicant managed up to the commencement of the war by keeping a boarding house on the south-east coast but has had to close it down and is still responsible for various charges against the house Two children who help all they can Relieved once £15 Voted £2 and referred to the Guild —Widow aged 52, of M D Dub who practised at Widnes and died in 1915 Left totally unprovided for with three children only one of whom is working Applicant's health is very indifferent. Allowed to live rent free in a friend's house Relieved once £10 Voted £12 in 12 instalments —Daughter aged 56, of L.R C S Glasg who practised at Glasgow and died in 1883 *Endeavours to earn a living by teaching music* but cannot obtain sufficient pupils Only permanent income £25 Recommended by the Glasgow branch of the Guild. Relieved once £12 Voted £12 in 12 instalments —Widow aged 58 of L.S A Lond who practised at Limehouse and died in 1894 Applicant was left unprovided for with two young daughters both of whom are now working but only able to earn a little Earns a little by needlework but finds it difficult to meet expenses Relieved nine times £93 Voted £12 in 12 instalments.—Widow aged 71 of M D Edin who practised at Cambridge and died in 1908. Applicant endeavours to make a living by taking in boarders, but is not successful. Friends provide £18 per annum Relieved six times, £48 Voted £12 in 12 instalments —Wife aged 36 of M B Dub who practised in various places in England and Ireland Applicant had to leave him 18 months ago on account of his habits and cruelty One child 1½ years old Applicant is a trained nurse but unable to take permanent work on account of the child Relieved once £9 Voted £5 in two instalments —Widow aged 57 of L S A. Lond who practised at Islington and died in 1905 Applicant left unprovided for with two sons both of whom joined the Army one was killed and the other is missing Applicant is nearly blind and health is very precarious Relieved 12 times £145 Voted £18 in 12 instalments —Daughter aged 64 of M D Edin who practised in London and died in 1873 Applicant has two sisters and they endeavour to make a living by keeping a boarding house The recent death of the mother has depleted the family income, as she had a pension which died with her and the high cost of living makes it difficult to get on Relieved once £10 Voted £10 —Daughter aged 60 of M R C S Eng who practised at Yoxford and died in 1893 Has always had bad health and two relatives who used to help her have died Only income a pension of £29 from another society Relieved eight times £90 Voted £12 in 12 instalments —Daughter aged 69 of L.R C P Lond who practised at Brierley Hill and died in 1872 Has never been able to work through ill health and has recently fractured her ankle Only income a pension from another society of £25 Relieved nine times £65 Voted £12 in 12 instalments —Daughter aged 48 of M B Edin who practised at Southampton and died in 1886 Applicant is a trained midwife but owing to suffering from Bright's disease and heart trouble is unable to work Only income 10s 6d per week allowed by friends Relieved three times £24 Voted £12 in 12 instalments.—Widow aged 62, of L R C P Irel who practised at Liverpool and died in 1895 Applicant earns a living by nursing but owing to indifferent health and a bad cough unable to obtain permanent work and only earned £20 during the year Relieved four times, £29 Voted £12 in 12 instalments

The committee also granted special war time Christmas gifts of £1 each to 150 annuitants and 120 grantees Subscriptions may be sent to Dr Samuel West, hon treasurer, at 11, Chandos street, Cavendish square, London, W

THE KING has sanctioned the following promotions in the Order of the Hospital of St John of Jerusalem in England —Colonel Sir John Rose Bradford K C M G, C B, F R S, A M S Colonel Alfred Percy Blenkinsop C B, A M S, Colonel Sinclair Westcott, C B, C M G A M S and Surgeon General John Chislet Culling, A M S to be Knights of Grace, and Lieutenant-Colonel William Richard Blackwell R A M C, and Fleet-Surgeon Robert William Glennan Stewart R N,, to be Esquires

ROYAL SOCIETY OF ARTS (JOHN STREET, ADELPHI) —Amongst the lectures announced for the coming session are the following —W A M Goode, honorary secretary of the National Committee on "Relief Work in Belgium" (Jan 24th), Dr R Fortescue Fox on "The Future of British Spas" (Feb 7th) Lawrence Chubb, secretary of the Commons Preservation Society, on "Highways and Footpaths" The time in each case is 4 30 P M Admission is by ticket

Notes, Short Comments, and Answers to Correspondents.

HEALTH OF CEYLON

A REPORT prepared by Mr E Sueter, *Assistant Colonial* Secretary, on the affairs of Ceylon for the year 1915, *states* that the estimated population of the island (exclusive of *the military* and shipping) is about 4 424 300, an increase of nearly 107,600 on that of the previous year, due to an excess of about 51,100 births *over deaths and 55,000 arrivals* over departures of Indian coolies There are 113 males to every 100 females in the population of Ceylon The birth rate for the year was 37·0 per 1000 and the death rate 25·0 per 1000, *this latter being the lowest* on record since 1898, when improved registration began with the exception of the rate in 1904 when it was only 0 1 less 171 infants under one year died to every 1000 born, against an average of 195 This rate is the lowest recorded during *the preceding decennium The proportion* of deaths in the general community from certain principal causes to a million of the estimated population was as follows Infantile convulsions 2596, diarrhœa 2465, bronchitis and pneumonia, 1146, phthisis and other forms of *tuberculosis*, 952, *dysentery*, 774, ankylostomiasis, 468, malaria and malarial cachexia 390 premature birth and congenital defects, 307 cancer, 92, enteric fever, 88 and small pox, 35 Plague which broke out in 1914 for the first time in the history of *Ceylon*, is still *continuing, though the victims claimed in* the year under review are very much less, as will be seen by the following record Total cases in 1914, 413, ditto in in 1915, 139 total deaths in 1914, 381, ditto in 1915, 128 *On the other hand* and contrary to expectations, there was *no diminution* in the virulence of the disease the total case mortality being 92 per cent, as in the previous year 108 deaths per million were due to accidental drowning, 80 to falls from trees, and 53 to snake bite, 342 deaths were *attributed to homicide, against an average of* 181 This corresponded to *a rate of 77 per million—the highest* ever recorded in Ceylon—and was due to the riots in June The number of executions, too, rose to 76 from an average of 29, owing to the same cause

There are 78 Government *hospitals* (in addition to the lunatic and leper asylums) equipped with modern hospital furniture and surgical appliances The owners of estates have also provided 54 estate hospitals and 353 dispensaries Four new *hospitals* are under construction A general rebuilding scheme is in contemplation for the improvement of the Medical College The full course of training for medical students is five years, a diploma in medicine, surgery, and midwifery (which can be *registered in the United Kingdom*) is granted to successful medical students In Colombo there are a bacteriological institute an ophthalmic hospital, a lying in home, a hospital for women and children and one for infectious diseases, *there is also an establishment for the manufacture of calf lymph* The leper asylum, situated six miles from Colombo, contained 402 patients at the end of the year, the total treated during 1915 numbered 509 A smaller establishment for lepers exists at Kalmunai and has *accommodation for* 30, and it is now proposed to establish a leper colony at Mantivu in the Eastern Province

The highest annual rainfall registered was at *Carney* Estate, Ratnapura, which had a *total of* 266 8 inches, and the lowest was at Mantota in Mannar, which had a total of 25 85 The annual rainfall at Colombo (Cinnamon Gardens) was 96 81 inches The station showing the highest mean shade temperature *for* the year was Trincomalee with 84 4° F and the lowest Nuwara Eliya with 60 7° The figures for Colombo and Kandy were 81·0° and 77 1° respectively

STEAM DISINFECTING APPARATUS

WE have *received from* the Grampian Engineering Company, *Limited, of* Stirling, N B, and 43, Aldwych, London, W C, an interesting brochure on "Modern Steam *Disinfection*" in which are described the "Velox" *high pressure steam* and combined *current-steam* and vacuum formalin disinfectors. The merits of these methods of physical disinfection are closely discussed and full illustrations of the various types of apparatus are given *Practical* experiments are quoted demonstrating the sterilising efficiency *of the machines.*

T B—The statement was a definite and *precise* one and made as *long ago* as August 1st, 1916 In reply to a question by Mr J Anderson in the House of Commons, Mr Forster stated as follows "Instructions have been issued *to* recruiting medical boards *to* ask each man *definitely whether* (*a*) he *has* been under treatment in a sanatorium, (*b*) his name has been notified to the sanitary authorities as suffering from *consumption? No man* whose answer to either of these questions in the affirmative will be taken into the Army, but it will obviously be *necessary to verify his* statements." Mr Forster went on to add that the Local Government *Board had* arranged for local tuberculosis officers to supply particulars of all men of military age on the tuberculosis registers, and *that these* particulars would be supplied to the recruiting authorities *with instructions that such men* were not to be accepted for service In cases of doubt *the advice of* tuberculosis officers was to be asked for

N A M—A special course on the diagnosis and treatment of venereal diseases is being held for London panel practitioners at the Rochester Row Military Hospital, S W and this is *open to all medical men* Application should be made to Lieutenant-Colonel L W Harrison R A M C, at the hospital Lectures have been announced at the London and Guy's Hospitals and will doubtless be *arranged at other* metropolitan and provincial hospitals Details will be *given in our column devoted to control of* venereal diseases 'A System of Syphilis," edited by D'Arcy Power and Murphy (Oxford Medical Publications second edition *1914 Five volumes £2 2s*) is the most complete work *in English on the subject* "A Manual of Venereal *Diseases*" (same publisher second edition, 1913, 10*s* 6*d* net) is a practical volume The Report of the Royal Commission on Venereal Diseases is a mine of information on the whole subject

ERRATUM—In the Annus Medicus in THE LANCET of Dec 30th, 1916 (p 1116), under the heading of "Army Medical Service," we referred to the duplication of the office of Director-General and included the following phrase "While Sir Alfred Keogh, who had been Director General up *to 1910*, and *who* was in 1915 acting as Chief Commissioner for the British Red Cross Society in France and Belgium became Director General of the Army Medical Service at home" The year should have been stated as 1914 and not 1915

COMMUNICATIONS not noticed in our present issue will *receive attention in our next*

Medical Diary for the ensuing Week.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street W

MEETINGS OF SECTIONS

Tuesday Jan 16th

GENERAL MEETING OF FELLOWS: at 5 P M
Ballot for Election to the Fellowship

Wednesday Jan 17th.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles and reports should be written on one side of the paper only *and when accompanied by blocks it is requested that the name of the author and if possible of the article should be written on the blocks to facilitate identification*

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication sale and advertising departments of THE LANCET should be addressed "To the Manager"

We cannot undertake to return MSS not used

Offices 423, STRAND, LONDON W C

MANAGER'S NOTICES

ABSTRACT OF A

Hunterian Lecture

ON

PAGETS DISEASE OF THE NIPPLE *

Delivered before the Royal College of Surgeons of England on Feb 16th, 1917,

By W SAMPSON HANDLEY, M S Lond ,
F R C S Eng ,
HUNTERIAN PROFESSOR CAPTAIN R A.M.C.(T) SURGEON TO THE MIDDLESEX HOSPITAL.

(*From the Bland-Sutton Institute of Pathology, the Middlesex Hospital*)

Mr. President and Gentlemen,—It is impossible to lecture on Paget's Disease of the Nipple without quoting from his original paper,[1] not only as a token of respect to pioneer work, but also because little of importance has since been added to its discoverer's clinical description of the disease Moreover, it is impossible to summarise the paper, for it possesses in the highest degree those virtues of compression and concentration which are sometimes lacking in the medical writing of to-day Sir James Paget says —

> I believe it has not yet been published that certain chronic affections of the skin of the nipple and areola are very often succeeded by the formation of scirrhous cancer in the *mammary gland.* I have seen about 15 cases in which this has happened, and the events were in all of them so similar that one description may suffice
>
> The patients were all women, various in age from 40 to 60 or more years, having in common nothing remarkable but their disease In all of them the disease began as an eruption on the nipple and areola In the majority it had the appearance of a florid, intensely red, raw surface, very finely granular, as if nearly the whole thickness of the epidermis were removed, like the surface of very acute diffuse eczema or like that of an acute balanitis From such a surface, on the whole or greater part of the nipple and areola, there was always copious, clear, yellowish, viscid exudation
>
> It has happened that in every case which I have been able to watch, cancer of the mammary gland has followed within at the most two years and usually within one year The eruption has resisted all the treatment, both local and general, that has been used, and has continued even after the affected part of the skin has been involved in the cancerous disease
>
> The formation of cancer has not in any case taken place first in the diseased part of the skin It has always been in the substance in the mammary gland, beneath or not far from the diseased skin, and always with a clear interval of apparently healthy tissue

Subsequent Observations

Erichsen drew attention to the sharp definition of the eczematous patch, and made the important observation that the affected area is slightly indurated, a point of distinction from ordinary chronic eczema Wickham and Bowlby noted the flattening and disappearance of the nipple, sometimes passing into retraction, which is a constant feature of the disease

A specimen in the Museum of the Cancer Hospital, taken from a case under the care of Mr Charles Ryall, appears to indicate that Paget's disease may undergo complete spontaneous healing In this case a carcinoma is present in the subjacent breast Partial attempts at epitheliation are frequently seen in the diseased area

Histology

Two years after Paget's disease had been described the foundations of its histology were well and truly laid by Sir H T Butlin He found that the mucous layer of the epidermis of the eczematous skin underwent proliferation and increased in thickness It was occasionally traversed by fine fibrous bands, fibro-cells or spindle-cells The corium and subcutaneous tissue were indurated and infiltrated with small round cells (leucocytes) The milk ducts were widely open or distended They were not lined as in the normal condition by cylindrical epithelium, but contained frequently large masses of epithelium of the squamous or glandular form The connective tissue round the ducts was often infiltrated with small round cells. These changes in the ducts extended into the breast an inch or more beneath the nipple In one of the two cases examined the acini showed a proliferation similar to that often observed in the neighbourhood of carcinoma of the breast[2]

Butlin's observations are a very accurate description of the histological appearances. He inferred from them, as Paget did also, and both, I think, erroneously, that the eczema was the primary condition, and that the deeper changes were the result of it It is to be specially noticed that Butlin found *no* sign of malignancy in the surface epithelium, and he noted the interesting fact, to which I shall again refer, that it might be invaded by the connective tissue of the dermis He noted the induration and infiltration of the corium, which I believe to be an important guide to the pathogenesis of the disease

Enumeration of Erroneous Pathological Views.

Since 1876 the exact pathology of Paget's disease has remained a perennial subject of doubt and debate. It may be well at the outset to clear the ground by enumerating those views concerning it which are beyond doubt erroneous.

Is Paget's disease an ordinary eczema? On the joint authority of Dr Graham Little and of my colleague Dr Pringle, I can tell you that the microscopic appearances of Paget's disease are quite unlike those of an ordinary eczema Moreover, ordinary eczema of the nipple yields to treatment, and induration is absent in chronic eczema

Parasitic theory of Darier —In 1889 Darier found within the squamous epithelial cells of the diseased nipple certain peculiar appearances, now generally admitted to be the result of cell-degeneration, which he believed to indicate the presence of intracellular parasites His views gave rise to an extensive literature and to an admirable monograph by Wickham, but since he has had the courage and frankness to abandon them they need not further detain us

Distinction from squamous-celled carcinoma of the nipple —It is necessary to distinguish sharply between squamous-celled carcinoma of the nipple and Paget's disease Dr Browning has lent me a characteristic example of squamous carcinoma which I now show you In squamous celled carcinoma of the nipple there is seen a hard, elevated tumour of greater area than the normal nipple, which it replaces, and bounded by an everted or rampart-like edge. The flattened top of the swelling is irregular from ulceration, often sloughy, and it lacks the smoothness and brilliant colour which characterise Paget's disease Microscopically, squamous carcinoma presents the usual blunt down growing columns of prickle epithelium containing cell nests, while in Paget's disease, though the papillæ are exaggerated and the thickened stratum mucosum may show a few rudimentary cell nests there is no sign of invasion of the dermis by the overlying epidermis.

Paget stated rightly that the formation of cancer never takes place first in the diseased portion of the skin, though the eczematous surface might later become involved in the cancerous tissues from which at first it was separated by an interval

Several observers have found microscopic evidence in Paget's disease of epitheliomatous down growth such as precedes or constitutes a squamous carcinoma of the skin, among them are to be reckoned Darier, Karg, Fisse, and Rolleston and Hunt Butlin and Wickham found appearances suggestive of squamous carcinoma Bowlby, Unna, and G T Jackson reject the idea What is the reason for this conflict of evidence? It appears to depend first upon the fact that squamous carcinoma of the nipple is sometimes erroneously diagnosed as Paget's disease upon clinical examination But it chiefly arises from this circumstance that in Paget's disease there is elongation of the inter papillary columns of epithelium (Wickham, Bowlby, Rolleston and Hunt), together with an invasion of the epidermis by islets of fibrous tissue It will be shown later that this elongation is due to passive stretching, not to active down growth

We may, I think, dismiss the view that there is any real connexion between Paget's disease and squamous carcinoma of the nipple, though it still holds a place in some current text-books of pathology But a word must be said about a curious German variant of this theory

Intra-epidermal carcinoma —The degenerate deeper layers of the epidermis which contain the large clear cells known as Paget's cells, were taken by Schambacher to be a layer of malignant epithelium thrusting itself between the dermis and the superficial layers of the epidermis He and Jacobaeus thought they could sometimes trace a continuity between these cells and the cells of a glandular carcinoma of the breast beneath

---

* This lecture will appear in full with illustrations in an early number of the British Journal of Surgery

[1] Sir James Paget St. Bartholomew's Hospital Reports 1874, x

[2] The Minute Anatomy of Two Breasts the areolæ of which had been the seat of long-standing eczema, by Henry Trentham Butlin F R C S Surgical Registrar to St. Bartholomew's Hospital, Medico-Chirurgical Transactions, 1876, lix , 108-9

This is not the case in any specimen I have examined In some exceptional cases the carcinoma beneath may infiltrate up to the epidermis and its cells may abut on squamous epithelium But the relation is one of contiguity or slight intermixture, for as Fisso truly stated, the two varieties of cells remain easily distinguishable at a little distance from their point of contact [3]

CHANGES IN THE EPIDERMIS IN PAGET'S DISEASE

What, then, in point of fact are the changes which are found in the epidermis in Paget's disease? They may be divided into two stages, hypertrophic occurring at the periphery of the affected area, and atrophic occurring at its centre Over the whole area the horny epithelium has for the most exfoliated and disappeared

Hypertrophic Stage

Butlin, Thin, Duhring, and Wile drew attention to the proliferative thickening seen in the deeper layer, or stratum Malpighii of the epidermis This proliferation accounts for the slightly elevated, sharply defined border which clinically characterises the disease (Thin, Duhring, Wickham) Wickham accurately pictures the epidermis as riddled with vacuoles and presenting cellular disorganisation with consecutive proliferation The cells dissociate and lose their normal close cohesion The individual cells display the polymorphic degeneration on which the parasitic theory was founded Rifts and clefts appear in the close structure of the epithelium, more especially in the interpapillary processes which often display a central cavity or vacuole like space (Duhring and Wile) Duhring, Wile, Rolleston, and Hunt agree in describing this process as an œdematous degeneration of the epidermis, a description clinically confirmed by the thin alkaline discharge characteristic of the disease The length of the interpapillary columns of epithelium is much increased, sometimes to four times the normal But the naked eye, or a low power of the microscope, shows that the general boundary line between epidermis and dermis remains perfectly defined, without a suggestion of epitheliomatous downgrowth

Atrophic Stage

The gradual ruin of the epidermal architecture is hastened by intrusive bands of fibrous tissue or islets of round celled infiltration which insinuate themselves into the clefts of the moribund epidermis like ivy in an old wall The overgrown stratum Malpighii no longer holds together, and is reduced to a layer two or three cells thick, or is completely cast off in the discharge, exposing the tips of the papillæ The elongated interpapillary columns degenerate and disappear During this process islets of epithelium, which simulate epithelial downgrowths, are often for a time left embedded in the fibrous tissue But at a later stage the interpapillary columns have disappeared and the papillæ are in consequence laterally fused and unrecognisable Finally, and this stage is not often reached, the surface of the nipple is bare of epithelium, and is formed by a layer of granulation tissue

From this account it is obvious that the epidermis is the passive victim of deeper changes, not the assailant of the tissues beneath No analogy can be drawn between the flat florid weeping surface of Paget's disease, persisting for long periods without ulceration or fungation, and any known form of malignant disease Here I may turn aside for a moment to consider other cases in which degenerating or ill nourished epithelium suffers invasion by fibrous tissue

Invasion of the epithelial layer of the skin by fibrous tissue is a process which is very common though it is not recognised in works on pathology It may be studied at the bottom of the tonsillar crypts where the squamous epithelium is seen in the process of destruction by intrusive bands of fibrous tissue I have shown that de Morgan's spots, which are such common manifestations of cutaneous senility, are due to telangiectases occurring in intrusive islets of fibrous tissue embedded in the thickness of the epithelial layer of the skin [4]

Our discussion so far has led us to reject the parasitic theory of Paget's disease, to distinguish the affection sharply from epithelioma and to conclude with certainty that the surface epithelium of the affected nipple is not the seat of any malignant change, but that the changes in it are inflammatory or nutritional only and dependent upon œdema

CHANGES IN THE DERMIS

We have considered the changes in the epidermis, those in the dermis remain to be described

Broadly speaking they consist of œdematous swelling of the papillæ, with consequent stretching of the interpapillary columns of epithelium A band of round-celled infiltration is seen in the papillary layer, separated at first by a narrow interval of intact dermis from the overlying epithelium According to Unna, this band of infiltration is composed chiefly of plasma cells It lies in the plane in which the cutaneous lymphatics originate, a point to be especially noted In some specimens the band of infiltration is absent the superficial layer of the dermis is fibrotic, and the papillæ have disappeared, appearances indicating the fibrosis which ultimately results from round-celled infiltration The dermis is thickened, producing the superficial induration which is clinically evident

The deeper layers of the dermis though they show thickening, are otherwise little changed They show perivascular collections of round cells, and in some specimens groups of epithelial cells lying in lymphatic spaces can be seen This description, based upon my own observation, can be confirmed in every particular upon a perusal of the literature of the subject Broadly speaking, it shows a chronic œdema of the dermis with pachydermia

As the papillæ increase in size they stretch the interpapillary columns of epithelium and produce the deceptive appearance of downgrowth in these columns which has been noted by so many observers Later the mutual pressure of the swollen papillæ leads to the atrophy and disappearance of the interpapillary columns The fused papillæ are then no longer recognisable, and they appear to undergo a process of fibrosis which flattens them out The overlying epithelium, partly as the result of mechanical stretching and partly from œdema, suffers the changes already described It is probable that in these changes superficial bacterial infection plays some secondary part, though an undetermined one Of course, staphylococci are always present in the epidermis

CARCINOMA THE PRECURSOR OF PAGET'S DISEASE.

We must next consider a paper by Dr George Thin, published in 1881 Thin put forward the view that the primary lesion is an ordinary carcinoma of the breast, originating in the ducts, and that the changes in the nipple are secondary both in time and in importance As Thin truly says [5] —

> From what we know of the slow changes that frequently mark the earlier stages of cancer of the skin (in rodent cancer, for example) there can be little difficulty in accepting it as probable that cancerous changes are developing in the ducts long before they have given rise to sufficient induration to produce a palpable tumour

His paper marks, in my opinion, a great advance It has unfortunately been misunderstood owing to an unfortunate choice of title In order to distinguish Paget's eczema sharply from true eczema he suggested for the former condition the name "malignant papillary dermatitis" The word "malignant" is misleading, for it suggests what Dr Thin did not believe—the malignancy of the surface epithelium in Paget's disease

To prove in all cases the correctness of Thin's view that carcinoma of the breast precedes eczema is impossible But there is much evidence in its favour

Impalpable Carcinoma

A carcinoma of the breast may exist for years, may permeate the breast-lymphatics, may disseminate, and may cause death without ever giving rise to a palpable tumour in the breast Time forbids me to discuss this subject in detail and I have dealt with it fully elsewhere This drawing which I show you is an impalpable carcinoma arising in a breast rather shrunken and indurated by chronic mastitis The growth was not adherent to skin or fascia, and could not be distinguished by touch from the granular mastitic induration of the remaining part of the breast But it had already given rise to infection of the axillary glands at the time when I removed the breast

You are familiar with cases where a mass of carcinomatous glands develops in the axilla, secondary to a carcinoma of the breast which can only be detected by microscopic examination

---

[3] *Nature of the carcinoma accompanying Paget's disease*—In the microscopic examination of specimens of breast carcinoma accompanied by Paget's disease though most observers agree with Thin that the growth is usually a duct carcinoma doubt may arise whether the growth is an ordinary spheroidal-celled carcinoma. Sometimes the appearances of both forms of growth are present, as in Jordan Lloyd's case and in one of my own This difficulty has been cleared up by Lenthal Cheatle who has proved that many so-called spheroidal celled growths are really duct carcinomata in which the epithelium has lost its original columnar character

[4] Handley: Archives of the Middlesex Hospital

[5] Thin: Brit Med Jour May 14th and 21st 1831

In Paget's disease flattening or retraction of the nipple is an early sign, appearing long before a lump is felt in the breast It is recognised as peculiarly a sign of carcinoma Yet even at the time when a lump can be felt it is rare to find enlarged axillary glands (Wickham) The combination of characters—early retraction and long freedom of glands—indicates a chronic carcinoma of low virulence

There is, therefore, no improbability in the assumption that carcinoma precedes and causes Paget's disease even when no lump can be felt in the breast.

In this connexion Mr Lenthal Cheatle's case is of interest By his method of large sections cut with a giant microtome he found a minute focus of carcinoma in a breast the seat of Paget's disease, although clinically and macroscopically there was no sign of carcinoma in the breast

I may remind you that in not a single case of Paget's series did a carcinoma fail to show itself sooner or later, and in no case did the carcinoma first show itself in the diseased area of skin Jamieson, quoted by Sheild, relates a case in which Paget's disease persisted for 20 years without the development of a cancer in the breast. Even in such a case the presence of a cancer during the whole period cannot be excluded, for the life of a breast carcinoma may exceed this duration, and it is even possible that the growth might undergo spontaneous cure, leaving Paget's disease as a result

HOW DOES A CARCINOMA OF THE BREAST CAUSE PAGET'S DISEASE?

Accepting Thin's view that Paget's disease results from a pre-existing carcinoma we are arrested by the question, How does carcinoma cause Paget's disease?

Thin believed that the papillary dermatitis, or so-called Paget's eczema, resulted from the irritant action of an acrid cancerous discharge from the mouths of the milk ducts The suggestion is unconvincing, for Paget's disease may appear in cases where no moisture about the nipple has at any time been noticed

In approaching this question I will ask you to recall to your memory certain researches of mine on the dissemination of carcinoma which date back to the year 1904 It may now be regarded as established that the main factor in the dissemination of carcinoma is the process of permeation, the growth of tendril like cylinders of cancer cells along the easy routes provided by the lumina of the lymphatic vessels This process must be sharply distinguished from infiltration of the tissue interspaces

Obviously one of the results of permeation is to block the lymphatic vessels. It was, therefore, not surprising to find that lymphatic œdema frequently follows in the tissues whose lymph should normally drain away along the obstructed lymphatic vessels Œdema may sometimes come on before permeation has reached the lymphatic vessels of the œdematous part owing to a block lower down the course of the lymphatic stream

The commonest example of this condition is early cancer *en cuirasse* which in its origin, and apart from the nodular invasion by cancer which accompanies its later stages is a pure lymphatic œdema due to the blocking of the lymphatics of the subjacent fascial plexus by permeation I have suggested for it the name "cancerous pachydermia" The affected skin becomes thick and leathery, and in one early example which I examined the thin skin of the breast had attained a thickness of 6 mm, though it showed no sign of cancerous infiltration Sometimes but not usually, the affected skin becomes red and discoloured or again covered by eczematous crusts

Histologically the epithelium is found thin and atrophic with its horny layer peeling off Round-celled infiltration may be found in the superficial layers of the dermis, while in the deeper layers are perivascular collections of similar round cells, marking out the track of the obstructed lymphatics The papillæ of the dermis at first swollen by œdema, are later flattened out and obliterated by a secondary fibrosis

Causation by Œdema due to Permeation of Lymphatics

The similarity of these appearances with those seen in the skin of the nipple in Paget's disease was too strong to be overlooked and I formed the definite opinion that Paget's disease is due to lymphatic œdema of the nipple dependent on the blocking of the lymphatics by permeation extending from a pre-existing carcinoma of the breast The idea was confirmed by the definite papyraceous induration which is found in the affected area It explained the persistence of the smooth, red, raw area over long periods of time without marked tendency to ulcerate or fungate—facts impossible to associate with a surface composed of malignant tissue. The serous discharge was a lymphorrhœa from the blocked area of the skin The association of chronic "eczema" with lymphatic œdema is a familiar one, often seen on the legs in cases of elephantiasis and in other milder grades of lymphatic obstruction The peculiarities of Paget's "eczema" might be explained by the anatomical peculiarities of the nipple, its rich blood supply, its thin skin. The lymphatics of the ducts converging to the subareolar plexus would naturally carry permeation with especial rapidity to this plexus in the form of growth—namely duct cancer, which is particularly associated with Paget's disease Subsequent fibrosis of these lymphatics would naturally lead to flattening or retraction of the nipple

But upon consideration it appeared to me that the case thus made out was a *prima facie* one only Since 1904 I have taken such opportunities of examining cases of Paget's disease as have presented themselves, hoping to find a case in which permeation could be demonstrated. Meantime in 1912 I put my views briefly on record as a statement of opinion.[6]

The difficulty to be overcome lay in the fugitive nature of the process of permeation A permeated lymphatic becomes distended by the growth of the cancer cells within it, and an inflammatory reaction is thus excited Round-celled infiltration is followed by fibrous tissue formation and the included cylinder of cancer cells is ultimately strangled by the contraction of this newly formed fibrous tissue The original lymphatic is now represented by a solid fibrous thread and all local traces of the carcinoma have disappeared leaving lymphatic obstruction as a legacy

It was not until after 12 years that by a fortunate chance I met with the very early example of Paget's disease which I shall now describe. It showed a perfect and nearly complete permeation of the lymphatic vessels of the "eczematous" area of skin (Figs 1 and 2.) In looking at the section I was able in some degree to share the sensations of the astronomer Adams when he first beheld the planet of his calculations in its predicted position.

A healthy looking and well-developed man of 49 was recently sent to me by Dr J W F Jewell The patient noticed a button like induration of the right nipple four months before he sought medical advice. There had been no pain and no discharge from the nipple. The nipple was flattened, while the areola slightly raised above the surrounding surface, presented a bright red, slightly granular, dry surface with a few epidermal scales adherent to it Beneath the indurated nipple was a little hard growth adherent to the overlying skin, but movable on the fascia beneath The glands in the right axilla were hard and slightly enlarged The growth was removed, together with the pectorals and the axillary glands, and the patient made a good recovery

Histologically the axillary glands were free from growth The primary growth was a very cellular carcinoma sharply marked off from the surrounding tissues. Its infiltrative powers were therefore rather low On its cutaneous surface however, it had obtained access to the subareolar lymphatic plexus and so to the cutaneous lymphatics These vessels were completely and perfectly injected as by an artificial injection fluid In the papillary processes of the dermis the blunt finger like dilated vessels forming the commencement of the lymphatic system were distended by cancer cells exactly like the cells of the growth (Fig 1) The appearance presented is just that of a dilated lacteal in an intestinal villus Running out of ampullæ of origin are narrower vessels which can be seen in some sections uniting in the superficial layers of the dermis to form vessels of capillary size presenting the moniliform dilatations which characterise lymphatic vessels These vessels take a course vertical or oblique to the skin surface and in the sections are often cut longitudinally and present Y-shaped junctions They run down to, and enter the subareolar plexus which is seen lying between the skin and the closely subjacent breast tissue as a number of vessels of larger diameter cut for the most part transversely, since the section is at right angles to the plane of the plexus

Serial sections afford clear proof that the longitudinally cut groups of cancer cells really lie in cylindrical vessels and not in chink like spaces. The whole arrangement of the vessels stamps them as belonging to the lymphatic and not the blood vascular system

---

[6] Choyce's System of Surgery, vol ii., p 12.

In horizontal sections the comparison of the cancer filled spaces in the papillæ with the lacteal of an intestinal villus still holds good In such sections passing just deep to the apices of the papillæ a circular group of cancer cells occupies the middle of each papilla This appearance could never be produced by *fortuitous* infiltration It indicates with certainty that the cancer cells occupy pre formed anatomical *spaces—namely*, the vessels of origin of the lymphatic system (Fig 2)

Evidence Afforded by Above Case

A superficial critic might assert that what I have taken to be lymphatic vessels are in truth excretory ducts, passing to open on the surface of the skin A careful search through all my sections has shown that a *zone of dermis* invariably intervenes between the groups of cancer cells and the under surface of the epidermis Moreover, it is *obvious* that the apices of the V shaped unions of the *vessels* in question are directed away from the skin surface, not towards it, as would be the case if they belonged to the excretory apparatus of the skin Moreover, in numerous sections of the normal nipple no similar appearance could be detected

To complete the proof that my section shows lymphatics infected by cancer I attempted artificial injection of the lymphatics of the nipple with soluble Prussian blue My efforts in this direction have been limited by the preoccupations *of the war* But in one successful case the Prussian blue penetrated the papillæ of the skin almost to their tips, occupying the same central position as the cancer filled spaces in my specimen This *specimen* of injected skin must be allowed considerable anatomical value as demonstrating—so far as I know for the first time—the anatomy *of the origins of the* human cutaneous lymphatics It seems possible that this knowledge may be the key to advances in our knowledge of the pathology of various diseases of the skin

In regard to the actual measurements of my specimen of Paget's disease—

Over an area of 2 5 mm the epidermis is reduced to a layer consisting *of a thin sheet of* the rete Malpighii with deeply extending interpapillary processes as much as 6 mm in length —i e., about four times the normal length Beyond the periphery of this circle is an area of hypertrophied and thickened epidermis forming a circle with an outside diameter of 6 mm Here also the interpapillary columns of epithelium are much elongated This is due, not to down growth of the epithelium, but to œdematous hypertrophy of the papillæ of the corium, with consequent stretching of the interpapillary columns, for in the centre of the area the interpapillary columns are undergoing atrophy and some of them have disappeared altogether

Permeation of the skin lymphatics is recognisable over a circle 6 5 mm in diameter, and extends therefore just a little beyond the point where marked changes in the epithelium cease Permeation of the subareolar plexus extends over an area of 10 mm

These measurements show beneath the circular red area of dermatitis a larger circular area of permeated lymphatics, and beneath this again a still larger circular area of permeated deep lymphatics belonging to the subareolar plexus

Now the tendency of Paget's disease to spread centrifugally from its point of origin is a commonplace It may be inferred that that plane of the superficial tissues in which the affected circle is largest is the plane first affected The relative size of the infection circles measures in terms of space the lapse of time since each of the layers was invaded, and therefore the order of their invasion That is to say, the growth at first extends from the breast to the subareolar plexus and blocks it by permeation Next the process extends to the tributary lymphatics running from the skin to the subareolar plexus Lastly, as a result of lymph stasis from permeation œdematous hypertrophy of the papillæ is seen and nutrition fails in an area of the overlying epidermis

It is possible, of course, to conceive of the process reversed, and to assume that it *spreads more rapidly* once it reaches the subareolar plexus But the permeation of the lymphatics of the dermis cannot possibly be the result of the changes in the epidermis For the cells contained in these permeated lymphatics are not cutaneous cells but cells originating from the mammary epithelium For this reason I am entitled to conclude that the changes in the epidermis are secondary to the permeation *of the* dermal lymphatics, that the "eczema" is secondary to a pre existing carcinoma.

A third possibility remains, that the dermatitis and the permeation of the dermal lymphatics are independent events If so, how comes it that the areas are concentric? At either edge of the circles permeation of the dermal lymphatics is seen extending under œdematous skin just beyond the edge of the eczematous area *If this is* chance, books of logic might as well be burnt.

In this case the eczema had been present for four months only, whereas the average duration of the disease at the time of operation is something more like *four years* ample *time for the fibrotic processes* to destroy the lymphatics and *obliterate all* evidence of pathogenesis It is probably useless to look for permeation in the skin if the eczema is of long standing Those who would ask for evidence of permeation *in every case of Paget's* disease—who demand it to be shown in every case of a large series—fail to appreciate that disease is a biograph film and *not a* static entity, and that only one picture on the film one page torn from the novel, can be fixed and examined in any one case In most cases the picture or the page is inconclusive or insignificant Sometimes it reveals the essential secret.

The evidence of this case does not stand alone

A figure of Wickham's[7] (Plate II, Fig 2) almost duplicates the specimen I have just demonstrated It shows permeation extending under normal epithelium, while beneath the eczematous areas are permeated lymphatics distended by proliferated cancer cells, running vertically upwards into the papillary zone of the dermis Wickham appears to have considered that the epithelial masses were down growing processes of the epidermis His figure proves the incorrectness of this view, for the largest of these masses, though it touches the under surface of the epidermis, is sharply defined from it

Dubring and Wile found in the middle and lower layers of the corium alveoli of varying size, some of them "linear" containing typical carcinomatous epithelium These were present in both the cases they examined, and their observation distinctly points to permeation of the dermal lymphatics It is the more important in view of the general accuracy of their histological descriptions

I have also found evidence of persisting permeation in the deeper layers of the dermis in several cases of Paget's disease

Pathological Picture of the Disease

If the early specimen I have submitted to you be taken as the key and starting point, the various isolated otherwise unintelligible, phenomena of Paget's disease fall into their places like pieces in a jig saw puzzle Let me briefly picture the pathology of the disease in the light thus afforded.

A carcinoma starts in the smaller ducts of the breast, perhaps exceptionally from the acini or the larger ducts Usually, without producing a palpable tumour, it permeates the breast lymphatics widely The rich plexus of lymphatic vessels around the ducts forms an especially easy and convenient channel for permeation, and the lymphatic block extends along them to the subareolar plexus beneath the nipple

The cutaneous lymphatics about the nipple are now dammed up so that lymph cannot return from them Later they are themselves permeated, but possibly this is not always the case At this stage, and before any lump has appeared in the breast, *the* skin of the nipple and the mucosa of the ducts begin to show changes dependent upon lymphatic obstruction The epithelium shows disintegration and degeneration of its superficial layers with proliferation of the deeper layers These changes are nutritional and non malignant The dermis becomes thickened by solid lymphatic œdema The lymphatics of origin in the superficial layer of the dermis may be found filled with cancer cells, which are *also to* be seen in the lymphatics of the subareolar plexus

The permeated lymphatics now undergo the usual process of perilymphatic fibrosis, they become surrounded by aggregations of inflammatory round cells, and later by young fibrous tissue, which contracts upon and destroys the included cancer cells In most cases at the time the disease is removed the destruction of the cancer cells has been consummated, and there is seen merely a band of round celled infiltration in the superficial dermis while in the deeper dermis perivascular aggregations of round cells indicate the destruction of the lymphatics which are known to accompany the blood vessels in this layer In other and later cases organisation into fibrous tissue is complete, round cells have disappeared, the papillæ have been destroyed by the fibrous contraction which has taken place in them, and nothing remains to show that the lymphatic vessels of the dermis have been obliterated and replaced by fibrous cords save and except the persistent changes in the epithelium and the œdematous thickening of the dermis

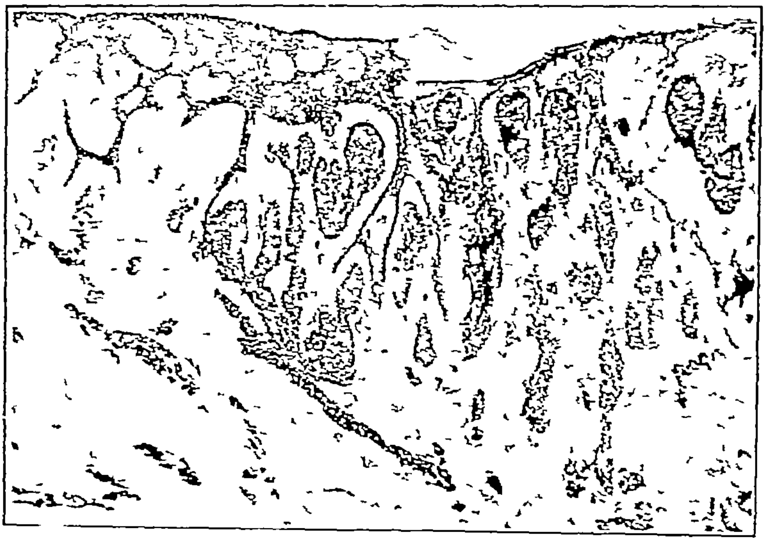
---

[7] Wickham Louis: Maladie de Paget Paris Masson 1890

In regard to the changes in the large ducts, these are evidently similar in nature to those found on the surface of the nipple, and they depend upon the same cause—namely lymphatic obstruction from permeation and subsequent fibrosis The only difference is that the shed epithelium cannot get away, and it remains *in situ* plugging and distending the ducts with a degenerate mass of débris

Lastly, even in the rare cases where though the Paget's disease has lasted many years, yet no carcinoma has made its appearance, it is probable that an atrophic scirrhus, which may have undergone partial or complete cure, preceded the onset of the Paget's disease But the possibility that the lymphatic obstruction in such cases is of inflammatory origin, and due to a chronic lymphangitis, cannot be altogether excluded

FIG 1



Vertical section through the edge of the area of Paget's disease showing the lymphatics of the dermis permeated and distended by cancer cells derived from the subjacent carcinoma. (Magnification 63 times)

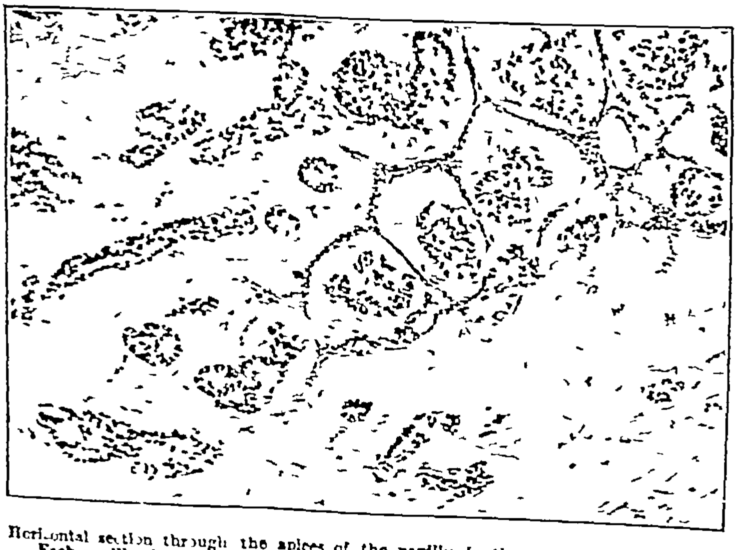
TREATMENT

It is sometimes stated, and more often thought, that pathology is no occupation for a serious-minded surgeon If this is true no sportsman should study the habits of his game Disease is the surgeon's quarry but he should walk it up casually by clinical observation or get it driven by pathological beaters The history of the treatment of Paget's eczema supplies a criticism of this theory Even so distinguished a man as Sir James Paget, led astray by superficial appearances and confessedly ignorant of its pathology, advocated a radically unsound method of treating the disease which he described so well He advised free excision of the eczematous area of the nipple a natural step to take if the eczema were in truth the precursor and cause of the cancer He admitted his want of success in preventing the development of cancer

Though, as the result of Thin's work, opinion has gradually turned in favour of treating such cases as ordinary carcinomata, a remaining doubt has often led to a dangerous delay and to the adoption of half hearted measures If it is once generally admitted that Paget's eczema is not the possible cause of a future carcinoma of the breast, but the result of an existing one—if, moreover, it is accepted as evidence that the growth has already widely permeated the breast—even though no palpable lump can be felt in it—then there will be no excuse for dilatory methods

The right treatment for Paget's disease is the usual complete operation for cancer of the breast It is my impression that duct-carcinoma the form of disease connected with Paget's disease, has a rather more favourable prognosis than carcinoma of the breast in general, and that it affects the axillary glands rather late Surgeon General Lenthal Cheatle tells me that, in his opinion, the post-operative prognosis of Paget's disease with carcinoma is a favourable one. The disease is so rare that statistics on the point are not available

FIG 2



Horizontal section through the apices of the papillæ in the area of Paget's disease Each papilla shows a central lymphatic permeated by cancer cells (Magnification 110 times)

CONCLUSION

It has been said that the ultimate test of a theory is its fruitfulness I may be permitted a certain satisfaction if—as I believe this lecture shows—the permeation theory of dissemination has emerged successfully from this final test

I have to thank Dr Browning director of the Bland Sutton Institute of Pathology at the Middlesex Hospital, for his kindness in placing the resources of the laboratories at my disposal for the purposes of this lecture, and for his suggestions as to methods of lymphatic injection Surgeon-General Cheatle has kindly allowed me to use his histological specimens

In conclusion, Sir, may I take this opportunity of thanking you, as representing this College, for the unsought recognition of my work implied in the recent grant to me of the quinquennial Walker prize for cancer research, an encouragement which has led me to present to you my views on Paget's disease

THE TREATMENT OF

SEVERE INFECTED GUNSHOT INJURIES OF THE SHOULDER AND ELBOW JOINTS,

EARLY EXCISION TO SECURE MOBILITY*

BY R H JOCELYN SWAN, M S LOND , F R C S ENG ,
MAJOR, R.A M C SENIOR SURGEON AND SURGICAL SPECIALIST ROYAL HERBERT HOSPITAL WOOLWICH SURGEON CANCER HOSPITAL, ETC

THE treatment of gunshot injuries to important joints, complicated by extensive comminution of the articular surfaces and by septic infection has received considerable attention, particularly in regard to the knee joint, where the anatomical conformation of the synovial membrane offers such difficulty in securing adequate drainage In a large number of severe injuries of the knee the best that can be hoped for, short of amputation, is an ankylosed joint, and the patient is left with a good prospect of earning his living A fixed shoulder or elbow, however, causes much greater physical disability as far as the earning capacity of the individual is concerned, and it is with the object of obtaining a movable and useful joint that I have adopted a method of early excision of the joint with such satisfactory results that I am tempted to put them together, with the hope that they may prove of assistance to others

The ultimate results obtained in the earlier period of the war after extensive injuries of both the shoulder and elbow joints were by no means satisfactory, drainage of the joint resulting in fixation of the articular surfaces, whilst sinus formation from necrosing fragments of bone often necessitated further operative measures before healing was obtained Fixation of the shoulder, with inability to abduct, flex, extend, or rotate the arm, is a serious disability whilst in the elbow any fixation at an angle about 80° renders the arm useless for feeding, whereas an elbow fixed at this angle is of very limited use for mechanical purposes In my earlier cases I considered it advisable to leave the joint alone after free drainage and removal of any obviously loose fragments of bone until firm healing was obtained and then proceeded to a formal excision of the joint but I found so much matting and infiltration of the ligaments, muscles, and structures in immediate relation to the joint from the previous septic inflammation, that not only was the operation rendered difficult, but the results obtained were not satisfactory In addition the time occupied in the healing of the original wounds, the liability to localised necrosis requiring local operations, and the pain experienced were a severe tax on the patient's strength and he was often inclined to refuse further operative procedure

In reviewing a large number of cases of gunshot wounds of the shoulder and elbow joints they may be roughly classified as (1) Penetrating wounds without fracture or sepsis , (2) penetrating wounds without fracture but with sepsis , (3) fracture of the articular surfaces without sepsis , and (4) fracture of the articular surfaces with sepsis

Each of these classes may be further complicated by the presence of a bullet or metal fragment, either embedded in the ends of the bone in the joint or in the tissue surrounding the joint In the majority of cases the bullet or fragment conveys infection with it from particles of earth or clothing accompanying it, and the question of removal must be decided upon in each individual case from the amount of trouble caused

The treatment of the joint depends as much upon the degree of sepsis arising as upon the anatomical injury produced Where no sepsis is present in the joint the wounds of entry and exit may be excised but not sutured, the joint fixed on some suitable splint and treated on general surgical lines Personally I must say that I regard the excision of primary gunshot wounds of a limited or even doubtful advantage, and have seen many cases of bad results from this practice Where septic infection has been conveyed to the interior of the joint more active measures must be adopted, and the joint cavity thoroughly irrigated

I would here note the difficulty in determining the presence of septic infection within the joint It has been frequently observed that the joint may be distended with pus containing streptococci, coliform organisms, and bacillus perfringens, but yet there is comparatively little pain, and the temperature and pulse rate are only slightly raised—in fact, a very different clinical feature to the acute septic arthritis of civil practice With a gunshot wound penetrating a joint, one may be tempted not to open the joint in the absence of constitutional disturbance, whereas delay where sepsis exists may make all the difference in the ultimate functional utility of the joint An inflamed area around the entrance or exit wound, the discharge of thin mucoid fluid on pressure, commencing thickening of the tissues around the joint, a slight elevation of temperature and a commencing leucocytosis are indications of infection and of the necessity of exploration and irrigation

It is, however, to cases of extensive bony injury to the articular surfaces, associated with a virulent infection, that I desire to draw attention These injuries are so extensive and appear at first sight so hopeless that the limb may be amputated, whereas if saved at the expense of a prolonged convalescence after free drainage and the removal of necrosing fragments of bone, the resulting fixation of the injured joint is a source of great physical disability to the patient The septic infiltration of the tissues surrounding the joint, together with the filling up of the actual fossæ in the bone around the joint by callus during the period in which the limb must be kept at rest, all tend to prevent mobility whilst the erosion of the articular cartilage in the pathological processes leads to absolute bony fixation

I was faced with this difficulty in a case of a young soldier whose right arm had been amputated immediately below the shoulder joint, and whose left elbow joint was extensively smashed and septic In this case fixation of the elbow at such an angle as to allow him to feed himself would have left him with an arm of little use for any other purposes, whilst fixation at 120°-150°, to give him the greatest mechanical advantage in the limb, would have rendered it useless for feeding After much consideration I decided to freely excise the damaged elbow joint, even in the presence of marked sepsis, leaving the cavity freely open and after three months this patient could flex and extend his elbow to a range of nearly 90°, and had excellent muscular power in the arm—in fact, he surprised us by lifting and flexing the elbow whilst holding a heavy scuttle of coals This case gave me much food for reflection, and I have since adopted the principle which I now advocate—namely, free and early excision in cases involving severe comminuted fracture of the articular surfaces of bone, complicated by septic infection with the direct object of obtaining a movable joint

The Treatment Adopted

Cases are received at Woolwich at varying periods from the date of injury but it is no uncommon thing for them to arrive within three days of being wounded In all septic cases I make a routine practice of giving an injection of a mixed polyvalent streptococcus and proteus vaccine as I have described elsewhere,[1] and the wounded area is carefully skiagraphed to determine the nature and extent of any bony injury and the presence of metal fragments I consider this preliminary injection of "antisepsis" vaccine of as much importance as the prophylactic injections of antitetanic serum as by its means the spread of anaerobic infection is limited

If the ends of the bone entering into the formation of the shoulder or elbow joint are severely fractured and if there is evidence of septic infection in the joint, I do not hesitate to open the latter freely, remove all completely detached fragments, and saw off the ends of the bone , the whole cavity is flushed with a forcible stream of hot sterile water and after arresting the bleeding gauze is very lightly inserted into the cavity, into which are brought three or four small perforated tubes attached to a reservoir containing Dakin's solution or hypertonic saline, by which the cavity is frequently flushed The incision is left freely open, perhaps one suture being used at the upper end In the case of the shoulder I make use of an oblique anterior incision between the deltoid and pectoralis major muscles opening the joint at the side of the long tendon of the biceps Frequently the actual damage to the bone is more severe than the radiograph would indicate, the head may be completely separated from the neck and displaced

---

* A paper read before the Surgical Section of the Royal Society of Medicine, March 14th 1917

[1] THE LANCET, 1916 ii 859

If possible, the tuberosities and rotator tendons are left intact, but if the fracture involves the tuberosities they are removed, the periosteum being stripped from the upper part of the shaft and the bone divided through the surgical neck. A stab incision is then made from the posterior aspect of the joint backwards to come out behind the shoulder, or the bullet track used if conveniently placed and a drainage tube inserted, the flushing tubes being introduced by the anterior incision. The arm is then fixed in a fully abducted and slightly flexed position, and in my later cases I have made use of a special splint I have had made for me by Messrs Allen and Hanbury for both these cases and for gunshot fractures of the upper third of the humerus, in the latter extension being maintained from the flexed elbow The arm rests very comfortably in this splint the wound can be easily dressed without removing it and the patient is able to be up and walk about, the deltoid muscle is maintained relaxed and does not show the same degree of wasting as when the arm is fixed to the side

In the elbow I use a free, median, posterior incision, separating the tissues close to the bone and as far as possible preserving the triceps tendinous attachment, and of course, the ulnar nerve The lower end of the humerus is projected from the wound and removed as may be found necessary usually above the epicondylar line The olecranon is removed together with the upper cartilaginous surface of the coronoid process and the cupped disc of the head of the radius The cavity is then flushed with hot sterile water, lightly filled with gauze, and the irrigation tubes introduced The arm is put up flexed, and supinated, the wound being left freely open After a few days when granulations appear on the surface, passive movements are commenced and the forearm put up in a different angle of extension each day As the wound fills up voluntary actions are encouraged

In two cases of severe fracture into the elbow I have been content with the removal of the fractured humeral condyle leaving the olecranon and radius untouched In each case the internal condyle and trochlear surface was removed at an early stage and the joint treated as in a complete excision At the operation cultures are taken from the interior of the joint and a full bacteriological examination made from which specific autogenous vaccines are prepared and given at intervals of four or five days under the direction of my colleague Dr Kenneth Goadby, who will detail the bacteriology of the cases

It might be noted here that the bacteriological findings in these cases show the presence of not only pyogenic cocci and bacilli of the coli group but also bacillus perfringens of malignant œdema and *Hibler IX*. The operations in practically all the cases were done in the presence of active and virulent sepsis but by treatment with free drainage irrigation, and vaccines the sepsis was at once controlled There is usually a slight elevation of temperature for a few days after operation but it soon settles down and in only one case have I had to incise the limb after the operation for any spread of sepsis

Results

So far I have operated in an early stage upon six cases for excision of the shoulder joint, and on eight for excision of the elbow joint in cases of severe comminution of the articular surfaces associated with sepsis

Shoulder joint cases —One remains in hospital but it is doing well, of the remaining five, in one a sinus remained after 17 weeks due to the necrosis of some small fragments which were removed Of these five cases the ultimate result was good in two free movement of flexion and extension and abduction without scapular movement to an angle from 50° to 60° with the vertical being obtained. In two other cases the result was fair flexion and extension being good but abduction was limited to 40° with the vertical whilst in the remaining one there was evidence of circumflex nerve injury from the primary wound which persisted so that abduction was impossible owing to the paralysis of the deltoid and the patient refused further operative treatment to deal with the nerve lesion It is interesting to note that in cases of excision of the shoulder where extensive removal of the bone through the surgical neck was performed by subperiosteal resection subsequent radiographs demonstrated that there was considerable reformation of bone in the line of the shaft of the humerus towards the glenoid cavity

Elbow-joint cases —Here the ultimate results have been even more satisfactory Of the eight cases operated upon one is still in hospital from operation too recent to include as a result, of the remaining seven cases, one required further operation on the ninth day from spread of sepsis in the middle of the arm Of these seven, in four the ultimate result exceeded all my expectations, flexion and extension being possible to almost full extent and supination and pronation being possible, but not perfect, all show some degree of lateral mobility but that does not interfere with the usefulness of the limb and the muscular power in the arm and forearm is excellent In each of these four cases flexion of the elbow is so good that the patient can voluntarily touch the shoulder of the same side can fix a collar stud at the back of the neck, and can touch the angle of the scapula of the opposite side, extension is in each possible to almost a straight line. Each one could lift and raise a fairly heavy ward chair with the elbow flexed and unaided In two cases flexion and extension are possible in a smaller range, in one from 80° to 145°, and in the other from 80° to 120°, further movement being limited by masses of callus formed about the ends of the bone In the latter case the operation for excision was performed at a later period after free drainage had proved ineffectual to arrest the infective processes In the remaining case in which the upper fourth of the radius had to be removed owing to excessive shattering flexion and extension are possible in a range of 45°, but no movement of pronation or supination is allowed owing to the absolute fixation of the upper end of the radius to the ulna by a large mass of callus joining the two bones

In addition to the above I have excised two hip-joints for extensive fracture of the head and neck of the femur with septic infection in the joint One case did well, and the patient walks with a limb shortened by 1¼ inches, but with good movement at the hip The other case was doing well, but died suddenly on the thirteenth day from a profuse hæmorrhage from a chronic duodenal ulcer which opened the pancreatico-duodenal artery So far I have had no opportunity of excising a knee-joint in a recent case of gunshot injury, but in the light of other joint cases and with my experience of the difficulty of adequately draining a septic knee joint, I would not hesitate to do so, but in this instance with the distinct object of obtaining a firmly ankylosed joint

I am of opinion that the earlier the operation of excision is performed the better is the chance of obtaining free mobility In my cases the best results have followed operations performed soon after the injury Naturally a very great deal of the success of the operation depends upon the assiduity of the after treatment and the hearty coöperation of the patient in carrying out early movements and I would here like to express my sincere thanks to the various medical officers who have had charge of these cases and who have so faithfully carried out my instructions

Advantages of the Operation

1 All loose fragments of bone and the articular surfaces are removed having a clean sawn surface rather than jagged ends of bone

2 Very free drainage is established and the joint can be freely irrigated

3 The septic processes are at once controlled and pain is much diminished The chance of having to amputate for advancing sepsis is much lessened

4 The time of convalescence is very much diminished and there is much less risk of localised necrosis of bone and sinus formation

5 A movable joint is obtained with good muscular powers

Objections to the Operation

1 *Shock* —There is necessarily more shock in an excision of a joint than in making free incisions for drainage but actually the shock is very slight. The operation can be easily performed in half an hour bleeding is easily controlled and no large nerves are divided as in amputation I have seen no necessity of amputation having to follow in any case from failure to control the sepsis but should it become necessary the previous excision of the joint would probably increase the risk. There has been no instance of secondary hæmorrhage

2 The fact that *freshly sawn surfaces of bone are exposed to septic infection* might seem to be a disadvantage, but with

the free drainage, intermittent flushing of the cavity, and the use of vaccines the risk of septic osteomyelitis appears to be small

3 The risk of a *flail joint resulting* This is a possibility which cannot be overlooked, especially in the elbow I can only say that I have not seen it in my cases, and I have removed so much bone that three fingers could easily be placed between the sawn ends with the forearm extended, but I have seen one case in which the joint was flail after an excision of the elbow performed at a later stage

4 The excessive formation of callus around the divided ends of the bone may limit free movement In cases in which the comminution of bone is excessive, or where splinters or minute particles of bone are conveyed into the surrounding tissues, this formation seems to be more excessive and may limit free movement, but where movement is commenced early, and the patient steadily perseveres with it, good range of movement is obtained In some cases it is surprising that such good movement is obtained where large masses of ossified callus surround the ends of the bone

It may be justly urged on theoretical grounds that it is unjustifiable to remove so much bone in the presence of active and virulent sepsis, or that I am urging a procedure which contravenes ordinary surgical principles, but I can only point out the success that has attended these operations I am conscious that the number of cases is small, but I have not included those in which the operation has been performed when the wounds were healed and the joint fixed or those in which the operation was done at a later stage when necrosis of the end of the bone had commenced However, I feel most strongly that if in these cases of septic gunshot fractures involving the joint excision or partial excision were performed soon after the injury, we should be doing more for the wounded man in putting him into a better position to earn his future livelihood would materially shorten his convalescence, and thus save the State not only much of the expenses during hospital treatment, but also the amounts paid in pensions

I must thank Colonel R J S Simpson A.D M S Woolwich, for permission to make use of the cases forming the basis of this communication, and my colleague, Dr Martin Berry, for the excellent series of radiographs used in illustrating it

Shoulder joint Cases

CASE 1—Private B Wounded Dec 3rd, 1915 Bullet entered at back of left shoulder and passed out by a large wound in front Operation in France, anterior wound incised and shoulder joint opened Jan 3rd, 1916 Admitted to Woolwich Free discharge from anterior wound, great pain on any movement of shoulder Deltoid paralysed and circumflex anæsthesia Skiagraph showed much comminution of head and neck of humerus head of bone turned, so that articular surface faced outwards Jan 6th Operation Wound opened, upper end of humerus of dark grey colour and articular cartilage removed Periosteum separated and bone divided through surgical neck Area flushed with hot saline and wound lightly packed with gauze with large drainage tubes Arm fixed abducted with extension from elbow Jan 19th Wound granulating well Temperature normal since operation Arm fixed on Hey Groves crutch splint No pain in shoulder Jan 27th General condition much improved Feb 14th Wound healed Passive movements are free, but patient will not make any attempt towards active movement Deltoid paralysed March 20th Flexion and extension good No abduction Deltoid wasted June 1st Can flex and extend shoulder, but no abduction Circumflex paralysis remains Movements of elbow and hand good Skiagraph showed large deposition of bone in line of shaft occupying position of piece removed No necrosis or sequestrum seen

CASE 2—Private H Wounded Dec 12th, 1915 bullet entering at point of right shoulder and coming out in pectoral fold Feb 27th, 1916 Sinuses remain at each wound and dead bone easily felt by probe Free discharge of thick pus Skiagraph showed disorganisation of head of humerus, articular surface pointed upwards Rarefied area in neck, probably necrotic March 4th Operation Much disorganisation found in shoulder joint the head of humerus being blackened and soft necrotic area below it Tuberosities not involved Section made through anatomical neck and necrotic area thoroughly scraped Cavity flushed out Free drainage Arm fixed in abducted position March 24th Slight pyrexia for first week Wound closing rapidly Passive movements commenced April 20th Wound healed Moves shoulder a little July 13th Can flex and extend arm and abduct to 40° Deltoid acts well No rotation in shoulder, but movements are increasing

CASE 3—Corporal G Wounded Jan 24th, 1916, bullet passing through right shoulder Two operations in France where shoulder joint opened and drained March 17th Two healed wounds on outer aspect of shoulder and large open wounds both in front and behind, through which a drainage tube passes Great pain in any movement. No paralysis of arm Skiagraph showed extensive comminution of upper end of humerus, the head being completely separated from the shaft, the drainage tube passing in interval Upper end of shaft necrotic March 28th Operation Anterior opening enlarged and joint opened Head of humerus very necrosed and devoid of articular cartilage Upper end of shaft also necrosed Periosteum separated and shaft divided through surgical neck, 1½ inches being removed Granulations scraped away and bleeding arrested by hot saline Cavity irrigated with hydrogen peroxide, large drainage tube in posterior wound and small tubes for irrigation from front wound Light pack of gauze in wound April 2nd Very little discharge and granulations appearing April 17th Wound healthy, passive movements commenced May 10th Not much active movement in arm yet July 15th Very fair movement in shoulder, flexion and extension good but abduction limited to 40° Skiagraph showed a new formation of bone extending in line of shaft towards glenoid cavity

CASE 4—Private G P Wounded July 1st, bullet entering front of left shoulder 1½ inches outside tip of coracoid process and emerging at slightly lower level behind Admitted July 5th, when a radiograph showed fracture of the clavicle, of the acromion process, and of the anatomical neck of the humerus, the head of the latter being comminuted and displaced July 6th Wounds opened and free drainage established through joint July 27th Temperature raised for last three days and local swelling about shoulder Wound opened and head of humerus found blackened and necrosed Decided to excise head periosteum peeled back and muscular attachments to tuberosities detached Resection through upper part of surgical neck Joint cavity flushed with hydrogen peroxide and saline and freely drained by posterior incision Intermittent flushing with Dakin's solution Arm maintained abducted Sept 25th Wounds all healed Nov 12th Can voluntarily abduct arm to 45° from body, and on fixing scapula passive movement can be made to 80° before scapula rotates Flexion and extension of arm good. Skiagraph showed a fair growth of callus around upper end of shaft Glenoid irregularly thickened Jan 4th, 1917 Movements at shoulder are more free Can abduct easily to 60° without rotation of scapula Flexion and extension are more free Result excellent (See Figs 1 and 2)

CASE 5—Private H MacI Wounded July 1st, 1916 by rifle bullet entering in front of right shoulder just outside tip of coracoid process and emerging in posterior deltoid margin Admitted July 4th Anterior wound sloughing Thin, serous bubbly pus draining Great pain in shoulder No nerve injury Skiagraph showed very comminuted fracture of head of humerus Articular surface rotated July 6th Operation Incision in pectoro-deltoid interval, joint opened Head of humerus much comminuted Upper end of shaft black and necrotic Periosteum stripped off tuberosities and detached bone and upper end of shaft removed Area flushed with peroxide and hot saline and cavity lightly packed with gauze Large drainage-tube through posterior wound Arm put up fully abducted and arranged for frequent flushing July 9th Temperature about 100° F Wound clean and commencing granulation July 20th Wound excellent Very little discharge August 22nd Arm removed from splint and passive movements commenced in shoulder Wound almost healed Nov 11th Small sinus remained in incision and skiagraph showed small sequestra at upper divided end of humerus Can move shoulder surprisingly well Can abduct to 45° without movement of scapula Nov 13th Sequestra removed Jan 10th, 1917 Wound healed Movements of arm increased Can abduct to 60° and flex and extend well Can passively raise arm to almost vertical Result is very good (See Figs 3 4, and 5)

CASE 6—Corporal E Wounded July 29th, 1916, by shell fragment entering posterior aspect of left shoulder and emerging at tip of coracoid process Admitted August 3rd Patient sallow and sweating Temperature 98° F Pulse 112 Wounds foul and fine crepitation felt around anterior aspect of shoulder Skiagraph showed great comminution of head of humerus, which is separated from shaft Glenoid cavity and neck of scapula comminuted Fracture of coracoid process and spine of scapula Three fairly large metallic fragments present Operation (on admission) Wound freely opened and direct communication made from front to back through joint Bone very comminuted and very foul Smear preparations showed numerous spore forming bacilli Area swabbed with peroxide and tubes arranged for continuous

irrigation Saline infusion August 6th General condition good Temperature 98·6° F Pulse 96 Tongue clean August 14th Condition unsatisfactory Temperature up to 102° in evenings but tongue moist Drainage not so free August 15th Operation Wounds freely opened Bone found blackened and very foul Much comminution Purulent granulations in medullary cavity of shaft Latter sawn through surgical neck. Glenoid cavity only held by triceps attachment and was removed and many rough pieces of bone removed with forceps Area flushed with saline and hydrogen peroxide and freely drained Arranged for continuous irrigation and arm put up abducted August 21st Temperature normal since operation. August 30th Doing well Arm maintained abducted to 60° Sept 20th Anterior wound healing well Oct 20th Skiagraph showed a lot of callus around upper end of humerus which moves with shaft Sequestra present at glenoid and upper end of shaft Dec 30th Sinuses remain at each end of incision Jan 9th 1917 Sinuses opened and sequestra removed There is a small amount of mobility at shoulder, and deltoid muscle acts Patient remains under treatment (See Figs 6, 7, and 8)

Elbow-Joint Cases

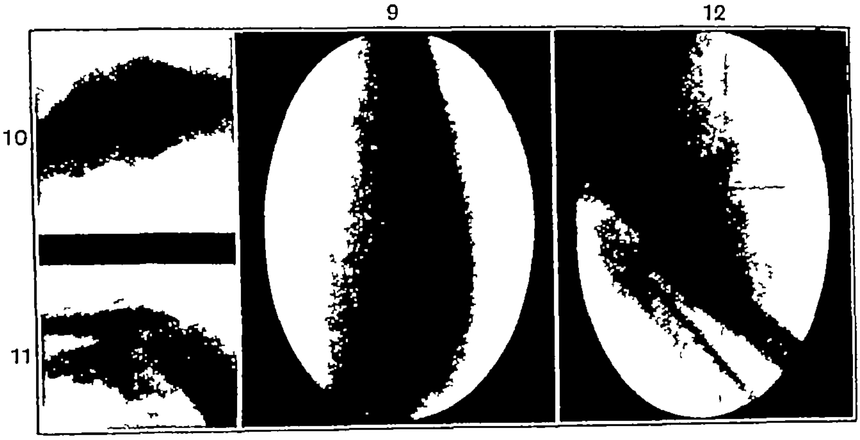
CASE A.—Private O Wounded May 28th, 1915, by shell explosion in close proximity, causing extensive wounds in right arm and about left elbow Was operated upon within two hours and right arm amputated immediately below shoulder joint Admitted June 5th Amputation stump very septic, wound extending into posterior axillary fold Also septic wound of upper left forearm over olecranon Skiagraph Complete shattering of upper 2 inches of both radius and ulna very comminuted No fracture of humerus Large metallic fragment 3 inches above joint June 8th General condition bad Pulse 120 Saline enemata Wound of forearm opened for drainage and fragment removed June 14th Operation Vertical median posterior incision and triceps

FIGS 9 10, 11 and 12 (Case A) — Fig 9 shows the great comminution of upper ends of radius and ulna, with fragments of bone driven into tissues in front of joint Figs 10 and 11 show antero posterior and lateral views of the joint six months after operation (Fig 11 is upside down) Fig 12 skiagraph after 18 months The large mass of callus in front of joint limited range of movement to 60°, but flexion was allowed to a right angle

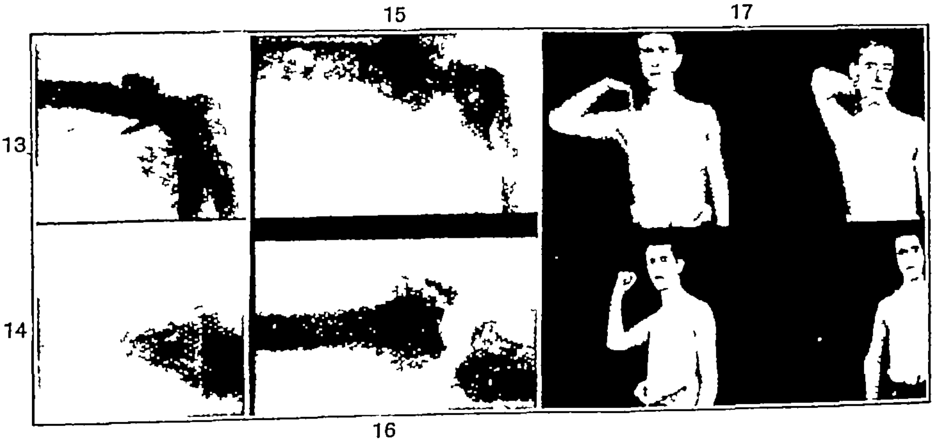
FIGS 13-17 (Case E) —Figs 13 and 14 are lateral and antero posterior radiographs taken four days after injury Figs 15 and 16 are taken ten weeks after excision of elbow note lateral formation of callus and slight internal displacement of forearm Fig 17 depicts the voluntary movement obtained

FIGS 18-22 (Case F) — Figs 18 and 19 show the fracture five days after injury; note the comminution of lower end of humerus Fig 20 six weeks after excision Figs 21 and 22, voluntary movement six weeks after excision these movements increased in range to those in Fig 17 (Case E) after a further interval of seven weeks

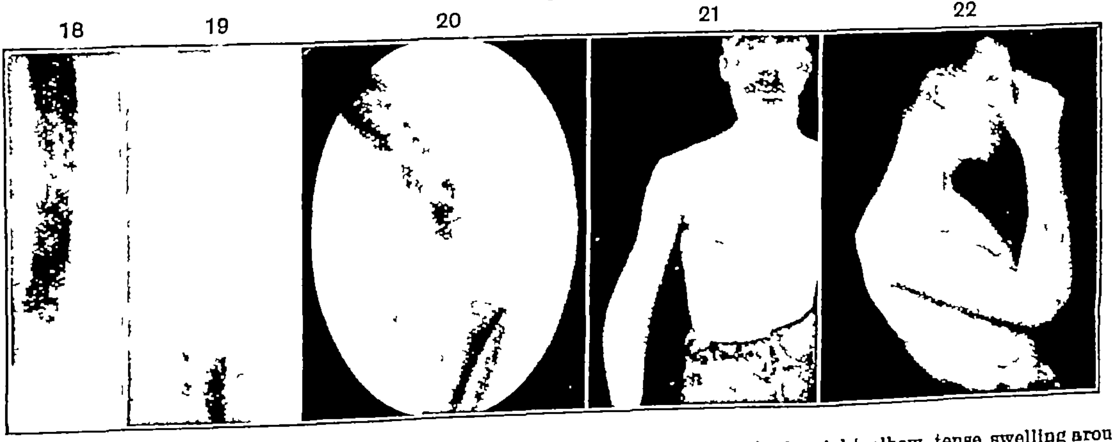
CASE A



CASE E



CASE F



tendon detached Detached fragments of bone removed and upper ends of radius and ulna sawn off just above the level of tubercle of radius Humerus not sawn off Area flushed with peroxide and cavity lightly packed No sutures in wound June 20th Wound clean and granulating July 2nd Passive movements commenced in elbow Can move fingers and hand well August 2nd Wound almost healed Only a small range of movements allowed without pain Jan 31st, 1916 Can move elbow through a range of 80° and has very good muscular power Can feed himself and touch back of occiput There is a firm prominence in front of elbow December Elbow had improved until he was again injured by bomb explosion Still has a range of movement of 60° and power is very good Skiagraph showed large formation of callus about upper end of radius and ulna which prevents full flexion at elbow (See Figs 9, 10, 11, and 12)

CASE B —Private E M Wounded Sept 25th, 1915 Wound in upper left forearm, involving median nerve, and also in inner aspect of right elbow joint Admitted Oct 14th, when there was great pain in right elbow, tense swelling around the joint, and a thick purulent discharge from the wounds Temperature 103 4°F Skiagraph showed shattering of lower end of right humerus No fracture of ulna or radius Oct 15th Operation Wounds of right elbow opened and found to pass directly into elbow joint, the inner part of which was destroyed Completely detached fragments of bone were removed, including the whole of inner condyle and supracondylar ridge and the trochlear surface of humerus Capitellar surface was intact Rough bone edges were rounded off and cavity flushed with hot saline and with peroxide Wound very lightly filled with gauze Arm put up on right-angle anterior splint The operation wound very quickly cleaned up and granulated Jan 1st, 1916 Wound healed and movements of elbow are good Jan 27th Can voluntarily move elbow from 80° to 160° The ulna has become slightly displaced inward as the result of the removal of the inner half of humeral articulation, but movement and muscular power are quite good

CASE C —Private M Wounded Sept 25th, 1915, in left forearm fracturing radius in upper third and also on inner aspect of right elbow joint Arrived Oct 15th From the wound of right elbow there was a profuse purulent discharge it was much swollen, extremely painful, and temperature 103° F Skiagraph showed an extensive comminution of lower end of humerus into elbow joint Radius and ulna were intact Oct 16th Operation Wounds opened and passed directly into elbow joint, the inner condyle of humerus was shattered All loose bone removed, including the whole of trochlear surface of humerus, internal condyle, and part of the internal supracondylar ridge The capitellar surface was left, together with the olecranon and head of the radius which were not fractured All rough edges of bone chipped away, cavity flushed with hot sterilised water and hydrogen peroxide Gauze lightly packed in and two small tubes passed in for intermittent flushing Oct 27th Elbow maintained flexed Wound clean and granulating Nov 23rd Wound nearly healed Passive movements in elbow good. Jan 1st, 1916 Wound of elbow healed Can flex voluntarily to 75° and extend to about 150° June 27th Movements of elbow from 70° to 150 Muscular power is very good Ulna is slightly displaced inward

CASE D —Sergeant S Wounded April 21st, 1916 shell fragment striking on tip of olecranon of right arm Operation in France, where large metal fragment and several pieces of bone removed On admission on May 1st there was a rounded opening over point of olecranon where bare fragments were exposed No exit wound Elbow very painful, and there was undue mobility forward of joint Temperature 99° F Skiagraph showed whole of olecranon comminuted into small fragments Fracture of lower end of humerus separating internal condyle and trochlear surface from rest of bone, extending into joint and displaced slightly forwards May 6th Operation Vertical posterior incision through triceps Many small fragments of olecranon removed and pus found in joint Base of olecranon sawn through Humeral fracture was in good position and so a complete excision was not performed Counter opening made on outer side and tubes arranged for continuous irrigation June 8th Temperature gradually settled down Very little movement allowed in elbow July 6th Has had a lot of pain in elbow and œdema around it Temperature 99–100° F July 8th Operation. Incision reopened and lower end of humerus found to be necrotic Further opening on inner side and joint irrigated July 20th Temperature 101° and much purulent discharge Operation Joint fully opened and cartilage found much eroded Complete excision removing humerus above intercondylar line base of olecranon and head of radius Light pack of gauze and small tubes for irrigation August 1st Doing well, wound clean Temperature normal August 30th Wound healed Can voluntarily flex elbow Sept 20th Can flex and extend from 80° to 120° Supination and pronation fair Oct 30th Much improved Can touch shoulder of same side Supination and pronation improved Muscular power good

CASE E —Private F Wounded July 1st, 1916 by bullet entering outer and anterior aspect of right arm 2½ inches above elbow and out over external condyle On admission, July 5th, both wounds were inflamed and surrounding tissues swollen Great pain in moving elbow Temperature 98 6° F Skiagraph showed fracture of lower end of humerus, extending into joint Much comminution especially of external condyle Radius and ulna intact Several small pieces of bone in tissues in front and behind joint July 9th Elbow very painful Temperature 99 6° Leucocyte count 13 500 July 11th Operation Median vertical incision and pieces of bone removed from triceps Joint freely opened and fracture found much more extensive than radiograph suggested, the whole of external condyle and capitellar surface and outer half of trochlear surface being completely detached comminuted and rotated outwards Section of humerus made ¾ inch above upper limit of olecranon fossa and olecranon removed at base leaving cartilage of coronoid process and head of radius intact owing to the extent of removal necessary in humerus Cavity flushed with hot water and upper part of incision and triceps sutured Free opening left below and tubes put in for intermittent flushing July 20th Spread of sepsis in arm Focus opened July 24th Temperature not raised since last operation Passive movements commenced. Wounds clean August 23rd Wound almost closed Voluntary movements increasing Sept 8th Wound healed Can flex elbow enough to feed himself and to light a cigarette. Sept 20th Can voluntarily flex to 80° and extend almost fully Supination and pronation very good December Can flex to 75° and extend almost to straight line Muscular power very good Excellent result (See Figs 13, 14 15 16, and 17)

CASE F —Private A. M Wounded July 29th 1916 bullet entering over tip of right olecranon and emerging at side of inner mid line of elbow joint On admission, August 3rd there was much ecchymosis of arm and forearm and swelling around the elbow joint Wounds small and clean Temperature 98 4° F Movements of elbow painful Skiagraph showed very extensive damage to lower end of humerus, both condyles being fractured from shaft into joint and separated by lower end of shaft Olecranon process also fractured August 6th Joint more swollen Temperature 99 8° Leucocyte count 15 000 August 7th Operation Posterior wound excised Vertical median posterior incision of joint opened Olecranon found fractured, together with a large triangular piece of upper shaft of ulna, which was removed Both humeral condyles detached and articular surface of humerus comminuted, the lower end of shaft impinging on ulna between the fractured condyles The muscular attachments were separated from condyles and later removed and lower end of humerus sawn off Olecranon and coronoid processes of ulna and head of radius removed Area well flushed with hot water and bleeding arrested Each end of wound sutured and large median opening left for irrigation tubes August 14th Temperature normal since operation Very little discharge Small drainage-tube only in cavity August 21st Wound granulating Passive movements begun Sept 12th Can voluntarily flex elbow to 90° Sept 29th Movements increasing, but muscular power poor Nov 20th Movements very much improved Can easily touch shoulder of same side, back of neck, and scapula of left side Can extend to practically straight line Can supinate but cannot completely pronate Some lateral movement in elbow Muscular power good An excellent result (See Figs 18, 19, 20, 21, and 22.)

CASE G —Private E A. Wounded Sept 10th, 1916, bullet passing through upper and outer part of right forearm just below elbow joint Admitted Sept 27th Wounds dirty and swelling about upper arm Great pain on any attempted movement of elbow No nerve injury Skiagraph showed a very comminuted fracture of head, neck, and upper shaft of radius Many small pieces of bone driven into surrounding tissues No fracture seen in ulna or humerus With such a comminution of radius and with sepsis in the elbow joint, I deemed it advisable to remove the upper end of radius and so ensure drainage and also to attempt to obtain mobility in the elbow Sept 29th Operation Vertical incision through posterior wound Radial head found loose and in small pieces, the articular ligament being destroyed Many completely separated pieces of bone were removed and the sharp upper end of shaft of radius cut off with forceps The elbow and superior radio-ulnar joints were fully exposed and flushed with hot saline and with hydrogen peroxide Area lightly packed with gauze with tubes for drainage Oct 20th Wounds granulating well Temperature normal Dec 14th Wounds healed Can voluntarily move elbow from 75° to 120° and this will probably further improve There is no movement of pronation or supination and a skiagraph shows a large mass of callus around the upper end of the radius, fixing it to ulna, which now shows a small linear fracture in same area Probably the excessive formation of callus is due to the great comminution of bone forced into the tissues by the "explosive" force at the original injury

CASE H —Lieutenant P P Wounded Sept 15th, 1916, by shell fragment on inner and posterior aspect of right elbow Has had five operations in France, but does not know what was done Admitted Nov 14th, when arm and forearm fixed in a straight Thomas splint, with extension There was a large granulating surface on inner and posterior aspect of right elbow and much loss of tissue Complete ulnar anæsthesia and paralysis Skiagraph showed internal condyle of humerus was missing and a fracture line through humeral articular surface separating trochlear from capitellar surface Olecranon was fractured at base and displaced, and there was much bone débris in tissues Nov 20th Temperature has been raised and more swelling around joint Wounds opened and articular surface found devoid of cartilage, roughened and eroded Counter openings made for free drainage Dec. 12th Skiagraph showed necrosis was extending Dec 15th Operation. Vertical median posterior incision Olecranon removed Humerus projected from wound and 1½ inches of lower end removed, but not up to limit of fracture-line on inner side Upper end of ulna and radius was necrosed, and so removed by saw through base of coronoid process and head of radius Bleeding arrested and area well flushed with hot water, and tubes arranged for intermittent flushing with Dakin's solution. There was 1¾ inches interval between sawn surfaces when forearm extended Dec 20th Temperature normal since operation Wound flushed very frequently with Dakin's solution, alternating was hypertonic saline Dec 27th Wound granulating rapidly Temperature normal Forearm fixed in different positions at daily dressing Jan 12th Granulations flush with surface and much smaller Can move elbow passively from 75° to 120° without pain March 1st Can voluntarily flex from 150° to 90° Remains under treatment

ON THE CULTIVATION OF THE MALARIAL PARASITE *IN VITRO* *

BY LEONARD S DUDGEON, F R C P LOND,
LIEUTENANT-COLONEL R A M C (TEMP) CONSULTING BACTERIOLOGIST SALONIKA ARMY
AND
CECIL CLARKE, M D LOND, M R C P LOND,
TEMPORARY CAPTAIN R.A M C OFFICER CONDUCTING MOBILE LABORATORY SALONIKA

IN the course of an investigation during the months of September and October, 1916, of cases of pyrexia admitted to a casualty clearing station as N Y D (not yet diagnosed) malaria, or jaundice, the usual methods of hæmoculture in bile salt media and citrated broth were supplemented, in addition to the examination of blood films for malaria, by the employment of a medium consisting of citrated normal saline containing varying strengths of glucose The object in view was the cultivation of the plasmodium in this medium At first the strengths of glucose used were 2 and 5 per cent, and later two other strengths, 7 5 and 10 per cent, were tried The strength of the sodium citrate in the medium was 1 5 per cent

The cultivation of the parasite was attempted in every instance of 100 cases of pyrexia, comprising enteric group infections, 20, N Y D, 49, and malaria, 31 In this first series a marked increase in the number of parasites in the culture tubes was noted in 9 of the 31 cases of malaria The present paper embodies the results obtained from 51 cases of clinical malaria examined by means of the following technique

Technique—Blood from a vein at the bend of the elbow was obtained either by direct puncture or by an all glass syringe with large bore needle About 1 to 2 c c of blood was inoculated into 10 c c of the glucose medium After thorough mixing the tubes were incubated at 40°C for 20 to 24 hours Both aerobic and anaerobic methods were employed Films were made from the uppermost layer of corpuscles, after the supernatant fluid had been pipetted off Stained by the Giemsa method and examined by oil immersion lens The control films of 51 cases showed —

Malignant malaria (ring forms and crescents or crescents only)	18
Benign tertian	12
Quartan	1
Malaria type undetermined	10
No malarial parasites	10

Culture

—	Increase of parasites			Totals	
	Marked	Not marked	Undetermined	Positive.	Negative
Malignant malaria	11	1	2	14	4
Benign tertian	0	0	1	1	12
Malaria ? type	4	0	3	7	3
Films negative	2	2	1	5	5
	17	3	7	27	24

Evidence of increase of parasites—Using this medium a diluted plasma with the addition of dextrose, the characteristic form which can be recognised as a plasmodium is what is termed here the "dot" form In size it is smaller than the fine ring, the nucleus staining as a bright-red dot and the protoplasm an intense blue, semilunar in shape The appearance suggests the merozoite Typical ring forms were infrequent Although the "dot" form appears free in many of the films, yet in fortunate films they are seen to be intracorpuscular, and it is probable that in the spreading of the films the fragile envelope of the incubated red corpuscle is damaged No comparative enumerations of parasites were attempted

Remarks—In 17 cases (all of which were undoubtedly malignant malaria) the terms "abundant," "very numerous," are employed to indicate the number of 'dot' forms present The mere words do not adequately convey to the mind the relative ease with which parasites are to be found in the films as compared with the original control film Of 18 cases of malignant malaria investigated only 4 gave a completely negative result in culture On the other hand, no increase of parasites could be demonstrated in 12 cases of benign tertian and in 1 of quartan infection Of 10 cases of malaria of undetermined type the culture was negative in 3 A reference to this point in connexion with diagnosis and the presence of quinine in the serum will be made later Of 10 cases, 9 of clinical malaria and 1 of jaundice, in which the control blood films after adequate examination were considered negative, "dot" forms were found in 5 In two instances they were abundant

Our statement that no parasites were found was the result of prolonged examination of blood films The whole question, however, of the number of parasites present in blood is dealt with in detail by Sir Ronald Ross in his text-book on the "Prevention of Malaria" (1911), but one sentence can be quoted from this work, as follows 'But for a broad general rule we may, I think, accept the principle (pending more exact researches) that if we cannot find the parasites after careful search their number is not usually sufficient to produce fever "

Interpretation of results—Two interpretations of this apparent increase of parasites seem possible (1) an actual increase in the number of parasites, and (2) an apparent increase due to a concentration effect To take the latter explanation As is well known, if citrated whole blood be centrifugalised or allowed to settle the leucocytes are found to occupy mainly the intermediate layer between the red blood cells and the supernatant fluid And yet it is in this intermediate layer that the malarial parasites are found To quote Bass[1] "The parasites live at the top of the column of the precipitated cells in a layer varying in thickness from one fiftieth to one twentieth of an inch All parasites beneath this layer die in from 2 to 20 hours, the time is dependent on factors which we have not determined" The same author has shown that the consistency of the protoplasm of the malarial plasmodium is less yielding than that of the red blood corpuscle. "Large æstivo-autumnal plasmodia are round or oval, the tertian variety are more or less flattened." Such differences in the physical characters of the infected red corpuscles may determine in part the zone the living plasmodium occupies—namely the intermediate layer It may be, therefore, that this technique is of value in concentrating in this layer the infected corpuscles

The alternative explanation is that an actual increase in the number of parasites has occurred—that is the parasites have multiplied If increase in the number of parasites indicates actual development then segmentation of a mature schizont must have taken place in the culture tube during the 20 to 24 hours' incubation As only merozoite forms were found in the cultures, and, moreover no further progress in the life cycle followed a further incubation it is manifest that this method allowed of the development for only a portion of the asexual cycle, in contradistinction to Bass's method, which permits of the cultivation of the parasite throughout one, or more than one generation In our experiments further incubation produced a gradual diminution in the number of parasites seen in the films It is admitted that the possibilities of this technique are confined to aiding clinical diagnosis

Blood incubated in citrated broth, but without the addition of dextrose, did not permit of the development of the 'dot" forms in the culture tubes The citrated plasma medium with dextrose may be said to permit of concentration of, and life of the plasmodium for a period of 24 hours or more, while with Bass's medium the patient's serum with dextrose permits of concentration plus life plus development of the plasmodium

Whether the true explanation of the results is an apparent or a real increase of parasites in the intermediate layer or both the evidence permits of no dogmatic opinion

Conditions of growth—The favourable conditions of growth are three —

1 The presence of dextrose in the medium, as already stated is essential Bass and Johns[1] in October 1912 published their discovery of this important factor Further they found that maltose alone of many carbohydrates tried —e g, saccharose lactose, galactose, dextrine, mannite—could replace dextrose[1]

The percentage of sugar in normal blood is about 0 1 per cent It has been shown by Maclean[3] that when normal blood is incubated for four hours at 37° C active glycolysis occurs owing to the action of the leucocytes Further Maclean has shown that normal blood is capable of glyco—

---

* A paper read before the Salonika Medical Society on Feb 14th 1917

lysis whether or not sugar is added He gives "0 4 per cent or so" as about the maximum of sugar met with in diabetic blood, and records an experiment with normal blood to which glucose had been added, so that the total amount was 0 358 per cent, while after three hours' incubation at 37° C the glucose was estimated at 0 281 per cent This is a distinct reduction, but on the lines of our experiments with amounts such as 2 5 and 10 per cent of added glucose it indicates that much of the added glucose is unaffected Accordingly, in our experiments dextrose was added to the medium in quantities sufficient to obviate this diminution in dextrose content by the leucocytes Strengths of dextrose varying from 2 per cent to 10 per cent were tried and the best results obtained in the 5 and 7 5 per cent solution At variance with this conclusion is the recommendation of Bass, as to the strength of dextrose, in his second publication Bass using undiluted human serum as the culture medium added dextrose in such quantity that the final mixture contained 0 5 per cent dextrose The successful results obtained by Bass and Johns have been confirmed

2 Bass in his original paper emphasised the importance of strict *anaerobiosis*, but in the second publication the technique recommended does not necessitate anaerobic cultivation Whether the employment of glucose in the medium secures anaerobiosis or no certain it is that, using both anaerobic and aerobic methods, we achieved precisely the same results The red corpuscles by reason of their avidity for oxygen seem to remove the oxygen from the fluid medium and so contribute to the maintenance of an anaerobic state

3 The optimum *temperature* is given as 40° C Bass noted the segmentation of æstivo-autumnal parasites from the smallest rings in about 30 hours at 40° C, and that the parasite will develop but more slowly, at any temperature between 37° and 40° C In this series all cultures were incubated at 40° C

Attempts to cultivate the benign tertian parasite, as already noted, have with this technique so far met with no success How different is the case of the malignant parasite which can live and develop partially in an unfavourable culture medium! Now, as Bass has grown the three malarial parasites, a comparison of the two methods, based as yet on a small number of cases, is fitting

The literature of this subject which was not even available at the outset of these investigations, is limited to two papers Bass and Johns[1] have recorded that they successfully cultivated the æstivo autumnal parasite from each of 29 different patients and the benign tertian parasite six times One case of quartan was tested, but the parasites failed to grow The lack of success was ascribed to certain errors of technique "It is to be remembered that one of us (Bass[3]) obtained growth of the quartan parasite in his earlier work."

Thomson and McLellan,[4] employing Bass's method but incubating at the lower temperature of 38° C, were able to cultivate the malignant parasite from two patients The development of the plasmodium through one generation was followed Sir Ronald Ross was convinced, after examining the preparations of Bass and Thomson and McLellan, that the evidence of the successful cultivation of plasmodium falciparum up to the sporulating forms was indisputable

Bass's original technique —One tenth of a cubic centimetre of a 50 per cent dextrose solution (Merck's) for each 10 cubic centimetres of blood to be taken is placed in the defibrinating tube before the blood is drawn Defibrination is effected by gently stirring or whipping with the rod which extends through the wool plug The whipping in of air, causing bubbles, must be avoided The defibrinated dextrose blood, sufficient in amount to ensure of a depth of serum one half to one inch above the red cells when the latter have settled, is transferred to two culture tubes and incubated at 40° C The parasites may be examined at any interval by drawing a small quantity of cells from the intermediate layer by means of a capillary tube Fine capillary tubes should not be used as the infected red cells may be damaged Great care must be taken in handling tubes to keep them in the upright position To defibrinate the blood we used a bundle of stiff wire twigs attached to a glass rod extending through the wool plug

Remarks —The material at our disposal during the last six weeks has been principally the benign tertian parasite Nine cases have been examined by Bass's method, four of which have given a completely negative result These latter cases had received doses of quinine in liquid form of 20, 40, 20, 20 grains respectively In two instances the control film at the time of hæmoculture was negative The five patients from whom positive cultures were obtained had received respectively the following amounts of quinine—0, 0, 5, 15, 10 grains The parasite developed typically for 16, 45, 18, 17, 12 hours Increase in the number of parasites, as judged by a comparison of the control film with the culture film, was noted in three instances In the remaining two positive results the parasites were plentiful Development up to segmentation was seen in two cultures

Employing the citrated plasma medium, negative results were obtained in six cases of benign tertian infection One case of quartan malaria continued its development up to the formation of merozoites Increase of parasites was noted Three other negative results were recorded In two the control films showed a few crescents but no ring forms In the third case there were a few fine ring forms This patient had been given 40 grains of quinine during the preceding 24 hours The remaining positive result is of interest The patient had been taking 10 grains of quinine daily in tabloid form since leaving hospital in September, 1916 The control film showed scanty fine ring parasites with nucleus and vacuole but no crescents Development was followed for 38 hours with the appearance of the malignant parasite in culture The number of parasites was much increased and there was a tendency, as noted by others for the parasites to collect in groups In the citrated plasma medium numerous "dot" forms were found at 24 hours Fine ring forms were also seen

The influence of quinine in culture —It seems certain that the presence of quinine in the serum used in the culture medium influences the development of the plasmodium, the benign tertian parasite especially, *in vitro*

In the living body a marked diminution in the number of benign tertian parasites from the peripheral blood within 12 to 24 hours of the giving of quinine in doses of 15 to 20 grains is observed commonly Quinine given in fluid form by the mouth can be demonstrated in the urine after half an hour's interval, and by the end of 48 hours the greater part has been excreted chiefly by the urine and to a less extent by the sweat and bile Clearly, then, the actual serum used for the culture medium will, if the drug has been administered recently, contain a certain amount of quinine

The exact manner in which quinine exerts its destructive influence is still largely a matter of speculation Thomson and McLellan[4] noted incomplete segmentation of the æstivo autumnal parasite obtained from a patient who had been taking 5 grains habitually A parasite of the same species recovered from another patient who had not taken quinine grew abundantly Bass does not mention the influence of quinine in his cultures

Summary

The material embodied in the first portion of this paper, based on 51 cases, is probably large enough to admit of certain statements Cases of clinical malaria in which the blood films were negative have been confirmed by cultural methods Of 10 patients whose control blood films after careful examination were considered as negative, "dot" forms were found in five cultures The two tertian parasites behave differently in culture. Of 19 cases of malignant malaria, 4 only gave completely negative results in the citrate plasma medium, while 17 cases of the benign tertian parasite failed to grow under the same conditions As a corollary of this where film examinations are inconclusive as to the type of parasite, a positive culture in this medium points to malignant infection The employment of this medium as a routine in hæmoculture may prove to be of value in assisting and confirming a clinical diagnosis

If with improvement of technique on the lines of Bass's method the cultivation of all three varieties of the malarial parasite can be made certain and permit of exact study, a step will have been made towards solving some of the many problems of malaria awaiting solution

TETANUS AND ITS ANTITOXIN

WITH AN ILLUSTRATIVE CASE

By WILLIAM TURNER, M V O, M D EDIN,
MILTON HILL MILITARY HOSPITAL (GENERAL HOSPITAL NO 3 SOUTHERN COMMAND) BERKSHIRE

WHEN the medical history of the present war comes to be written one of its most interesting features will undoubtedly be that section relating to the incidence of tetanus amongst the wounded from the various fronts, and recording the success which has attended its preventive and curative treatment

From a comparatively early stage of hostilities in France antitetanic serum has been in use throughout the British Expeditionary Force for all wounds likely to have become contaminated, subcutaneous or intramuscular injections being given as early as possible and repeated as circumstances seemed to indicate How far this measure is to be regarded as having contributed to the saving of life and suffering will be definitely ascertained when full statistics have been tabulated That a large amount of success is to be attributed to this *prophylactic* measure is already admitted by all who have had the opportunity of studying cases of the disease brought from the seat of war to the military hospitals in this country To what extent tetanus antitoxin is to be recommended as a *curative* agent is a question which will also, doubtless, be largely elucidated by the teachings of the present war

The following case, which resulted in recovery, is typical of many met with in the home hospitals during the war, and also presents some interesting pathological features

On July 1st, 1916, in the attack on Montauban Lance Corporal —— was wounded on the right shoulder by two fragments of shrapnel No dressing till next morning, when a piece of metal and piece of khaki were removed from the larger wound Antitetanic injection given and a second injection next day at Boulogne

On July 10th, on admission to Milton Hill Hospital, Berkshire, the patient appeared in good health Examination of shoulder showed two unhealthy looking wounds on posterior aspect The upper and larger one, just behind and below the acromion, was a superficial granulating area about an inch across The lower wound, over posterior fold of axilla penetrated deeper, X rays disclosed a piece of metal embedded in muscles at bottom of wound Both wounds were decidedly septic and were treated by hot fomentations and rest to the arm After 10 days the wounds showed little disposition to heal

On July 23rd patient complained of some stiffness in the shoulder Next day the whole arm from shoulder to wrist was in a state of tonic rigidity, and acutely flexed at elbow, no actual pain when arm was kept at rest, no painful spasms as yet, uneasiness in throat and right side of neck, and difficulty in swallowing food, pulse and temperature normal In the afternoon Sir William Osler saw him and made the following note No fever, patient complains a little of pain in the epigastrium and back and right shoulder The arm is flexed at the elbow muscles stand out prominently and feel rigid Patient can flex and extend the fingers, but cannot extend the arm, forcible extension does not hurt him Pectoral muscles are not involved, deltoid feels stiff Patient cannot lift his head off the pillow He has occasional spasms of back and neck and arm with great pain He opens his mouth fairly well

By evening the paroxysms had increased in frequency and severity, as also in area involved The muscles of whole right side of body except those of the leg were in a state of tense rigidity the abdominal wall was retracted and hard as a board, the left side of the body, except the left side of the abdominal wall, was unaffected Jaw clenched, head turned to right side Painful paroxysms, affecting only the right side, were brought on by any attempt at movement

By lumbar puncture 6 drachms of cerebro spinal fluid[1] were drawn off and 2000 U S A. units of tetanus antitoxin injected into spinal canal, 2000 units also given intramuscularly, chloretone gr xxx. per rectum

July 25th - Patient slept at intervals during the night, but when awake suffered much from sickness and pain in head and legs, very profuse perspiration Although the arm and right side of body generally remained rigid, the tetanic spasms did not increase in severity during the night Another injection of chloretone gr xxx., per rectum and antitoxin, 2000 units, intramuscularly

On July 27th rigidity of right side and flexure of arm remained the same, the muscles of back of neck and posterior fold of axilla being specially hard, abdominal wall tensely contracted and very tender to touch The jaw could be opened but very slightly, "risus" well marked The arm could be forcibly extended to a considerable extent without pain, but on relaxing it it returned to its flexed position, and this was immediately followed by a painful spasm involving the whole right side Even the leg was then thrust out as in cramp, but the foot appeared unaffected Patient complained of sore throat and severe pain in epigastrium Retention of urine had been experienced, but catheter not required Antitoxin 2000 units intramuscularly Chloretone gr xxx. per rectum

On July 29th rigidity the same, several spasms noted during the night, confined chiefly to right upper quadrant of body Jaw immovably fixed, feeding difficult Only liquids could be taken, and the act of swallowing was very painful Masses of tough dark phlegm formed in the throat were got rid of with extreme difficulty Nutrient enemata commenced Patient still lay with head turned to right side, mouth also drawn a little to the right, and eyes sometimes involuntarily rolled to that side, tongue bitten during sleep

On July 31st the general condition was much the same A notable feature was that the hand and fingers had been quite freely movable all along Neither were they affected during the paroxysms of spasm

On August 1st, except that abdominal muscles were still very hard and tender the rigidity of the right side appeared to be relaxing The head could be moved a little from side to side but could not be raised Teeth firmly clenched but separated a little during sleep Painful spasms were still excited on small provocation

On August 5th the general rigidity of the arm and forearm, and the tendency to attacks of spasm, were gradually becoming less pronounced The jaws could be opened about half an inch, but the idea of solid food was dreaded The patient was seen by Sir David Ferrier, who observed

There is slight transitory ankle clonus in the right foot, no Babinski reaction, knee jerk slightly exaggerated The movements of the proximal muscles of the right limbs are involved in spasm, whilst the distal muscles (hand and foot muscles) are not affected The abdominal muscles are very rigid There is a certain amount of spasm of the thoracic muscles, but the expansion of the chest is found on measurement to be about normal The platysma, trapezius, and sternomastoid on right side are only slightly rigid The deltoid and biceps are very hard The arm is firmly flexed at the elbow It lies across the chest and cannot be voluntarily moved Forced extension immediately produces spasm '

On August 6th there was severe abdominal pain, mostly on left side On the 7th this pain extended down left leg which was much swollen from the knee downwards The internal saphenous vein was hard and very tender An attack of acute phlebitis, depending on a thrombus, probably of the iliac vein, had thus supervened For several days the swelling of the leg increased, and extended upwards to the groin, being accompanied by much pain, but only slight rise of temperature In a week the swelling began to subside, and in another week the phlebitis had practically gone, slight swelling and discoloration of the leg persisted, however, for several weeks

On August 13th, except for the muscles of right arm and forearm, which were still rigid, preventing full extension, the muscles of the right side were no longer in spasm They felt abnormally soft and flabby Patient was beginning to take solid food, but had a sensation as if his tongue were tied Painful spasms were still excited in the arm on attempts forcibly to extend it

From this time steady progress was made, but in spite of abundant nourishment and exercise the patient's whole muscular system was for months deficient in tone He was easily fatigued, and complained of pains in the calves of the legs, and aching in the muscles generally, after even slight exertion For a long time the arm movement was very imperfect, and the elbow could not be voluntarily, or even by force, brought into a straight position, or raised above the head There remained a good deal of tenderness on pressure over the shoulder joint and along the line of the cervical plexus

With regard to the prophylactic effect of tetanus antitoxin it is rational to conclude that it will vary according to the amount of toxic material introduced into a wound, as well as to the dose of antitoxin given It is also a well established fact that the effect will be largely influenced by the route of administration the intrathecal route having been found by far the most efficacious Thus the result of an injection of the serum may be (*a*) Complete neutralisation of the poison and non appearance of the disease,
of the period of incubation and late appear-
(delayed tetanus), (*c*) limitation of the

---

[1] Cerebro-spinal fluid examined was found to contain a faint trace of albumin no sugar no cells no deposit.

area affected by the disease (localised tetanus), (*d*) diminished severity in the manifestations of the disease (modified tetanus)

Clinical and also experimental evidence support the contention that each and all of these results have been attained During the later periods of the war, when prophylactic treatment has been almost universally resorted to amongst the wounded in the Western front, the fall in the incidence of tetanus has been very remarkable There is also evidence to show that wounds, in the discharges of which bacilli resembling *B tetani* were found, and which were subsequently treated by antitetanic serum, have not been followed by tetanus

The proportion of cases of tetanus with long incubation stage has largely increased since this mode of prophylactic treatment has become general The comparative increase in the number of cases of limited or localised tetanus is abundantly shown by more recent reports That the severity of the disease has been greatly mitigated by the prophylactic use of antitoxin is clearly shown by the marked decline in the mortality of the disease during recent years, both in this country and in America.

From considerations such as these the conclusion seems warrantable that the preventive treatment of tetanus by means of its antitoxin is a sound and beneficent measure which ought to be followed up to the fullest limits which experience dictates to be safe

The curative treatment of tetanus by this same agent stands on a somewhat different footing, but the increasing number of recoveries recorded in cases where it has been energetically employed encourages the hope that here also we possess a remedy of unquestionable value. I can recall a case which I treated some four years ago by the combined intrathecal and intramuscular injection of antitoxin This was a severe and rapidly developing form of the disease, exhibiting general tetanic convulsions with opisthotonos No prophylactic had been employed in this case, yet, contrary to my expectation, recovery took place In the case of Lance-Corporal ——, above recorded, the disease had secured a firm hold, and was rapidly increasing in severity up to the time of the first intrathecal injection From that time the virulence of the attack appeared to be arrested, and no extension of the area involved was afterwards noted The frequency of the paroxysms also seemed to be diminished in consequence of the treatment

Referring further to the lance-corporal's case there are one or two points of pathological interest The unhealthy appearance of the wounds on patient's admission ten days after their infliction and their resistance to careful treatment for a fortnight longer suggested the presence in the tissues of something more than the mere fragment of metal I have in several cases noted this unaccountable delay in healing in wounds subsequently followed by tetanus It may be that tetanus spores lodged in a wound have the effect of maintaining an unhealthy septic condition, and this delay in healing, in the absence of any other obvious cause, may put the surgeon on his guard as to the possibility of impending tetanus in any case which obstinately resists ordinary methods of treatment It may even lead to a diligent search being made in the discharges for the spores or bacilli of tetanus. A very notable circumstance in this case was the rapid improvement in the wounds which set in immediately after the first injection of antitoxin The discharge ceased within two days and the wounds rapidly cicatrised.

The localisation and limitation of the disease in the above case also deserve attention From beginning to end the attack may be described as strictly *unilateral* At no period was any portion of the left side involved in spasm, with the exception of the abdominal wall and other parts where the muscles of the two sides act in association. Even in these the contractions were more marked on the right side The anatomical continuity of the muscles of the two sides of the abdomen would account for the apparent spasm of the whole abdominal wall. It was also observed that throughout the attack the right hand and foot were entirely unaffected by spasm, voluntary movement and sensibility also being normal in both

These observations are corroborative of the theories (*a*) that the morbid condition in tetanus is primarily confined to the nerves spinal cord and subcortical centres in direct connexion with the seat of infection but that it may subsequently, in consequence of the intensity of the infection or in the absence of any counteracting influence, such as antitoxin, extend to the nerve centres generally, and thence involve the entire muscular system, and (*b*) that the channel of transmission of the tetanus toxin is principally the nerves leading from the point of infection, and not the blood current or the general lymphatic system.

With reference to the rigid condition of the arm and shoulder after the tetanic symptoms had passed off, the question arises, Was the stiffening, which persisted for many weeks, a result of (*a*) a fibrosis of the muscles mainly involved in the prolonged spasm, or (*b*) a periarthritis due to continued irritation of the metal which still was in close relation to the shoulder-joint, or (*c*) a nerve implication due to proximity of the metal to the sheaths of the brachial plexus? Probably all of these conditions participated in preventing for a long period the restoration of the arm to its full measure of utility

In contemplating the removal of the piece of metal still *in situ* it will have to be borne in mind that such an operation is fraught with considerable risk of re-exciting the disease, and that special precautions, including a preliminary injection of tetanus antitoxin, will have to be observed.

Yet another remarkable feature of the case was the occurrence of thrombosis with phlebitis of the iliac and femoral veins as a sequel to the tetanus attack I can find no record that this association has ever hitherto been observed.

A CONTRIBUTION TO THE STUDY OF DYSENTERY

By A. C INMAN, M A, M B Oxon,
SUPERINTENDENT OF LABORATORIES BROMPTON HOSPITAL, LONDON
TEMPORARY HONORARY CAPTAIN R.A.M.C

AND

D G LILLIE, M A Cantab,
LATE BIOLOGIST TO THE BRITISH ANTARCTIC EXPEDITION, 1910

(*An Interim Report to the Medical Research Committee from the Laboratory, Mont Dore Military Hospital, Bournemouth*)

Early in October, 1916, it was ascertained by one of us (D G L) that carriers of *Entamœba histolytica* cysts were to be found among the dysentery convalescents invalided from France and Flanders It was therefore decided to search each convoy arriving from France for amœbic carriers as thoroughly as time allowed. Between Nov 3rd, 1916, and Jan 4th 1917, 159 dysentery convalescents were admitted to the hospital direct from France The incidence of carriers of *Entamœba histolytica* cysts among these 159 cases is indicated in Table I

Table I

Number of cases admitted.			Number of amœbic carriers discovered.		
British	Australian.	Other Colonial troops	British	Australian	Other Colonial troops
134	21	4	13	5	0

So that nearly 10 per cent. of the British cases and 24 per cent of the Australian cases were carrying *Entamœba histolytica* cysts

Now examination of the blood of these amœbic carriers revealed the fact that in 7 out of the 18 cases the blood serum agglutinated the *B dysenteriæ* Flexner or the *B dysenteriæ* Shiga in a dilution sufficiently high to warrant the diagnosis of a recent infection by one or other of these bacilli.[1]

This coincident finding of *Entamœba histolytica* cysts in the stools and specific agglutinating substances in the blood seemed sufficiently suggestive to warrant further observations

---

[1] The agglutination test was carried out by Dreyer's method with Standard Cultures prepared in the Department of Pathology University of Oxford on behalf of the Medical Research Committee In this report the test will merely be referred to as being positive or negative for the test and its diagnostic value will be fully dealt with in a separate report

TETANUS AND ITS ANTITOXIN

WITH AN ILLUSTRATIVE CASE

BY WILLIAM TURNER, M V O, M D EDIN,
MILTON HILL MILITARY HOSPITAL (GENERAL HOSPITAL NO 3 SOUTHERN COMMAND) BERKSHIRE.

WHEN the medical history of the present war comes to be written one of its most interesting features will undoubtedly be that section relating to the incidence of tetanus amongst the wounded from the various fronts, and recording the success which has attended its preventive and curative treatment

From a comparatively early stage of hostilities in France antitetanic serum has been in use throughout the British Expeditionary Force for all wounds likely to *have* become contaminated, subcutaneous or intramuscular injections being given as early as possible and repeated as circum stances seemed to indicate How far this measure is to be regarded as having contributed to the saving of life and suffering will be definitely ascertained when full statistics have been tabulated That a large amount of success is to be attributed to this *prophylactic* measure is already admitted by all who have had the opportunity of studying cases of the disease brought from the seat of war to the military hospitals in this country To what extent tetanus antitoxin is to be *recommended as a curative agent is a* question which will also doubtless, be largely elucidated by the teachings of the present war

The following case, which resulted in recovery, is typical of many met with in the home hospitals during the war, and also presents some interesting pathological features

On July 1st, 1916, in the *attack on Montauban, Lance* Corporal —— was wounded on the right shoulder by two fragments of shrapnel No dressing till next morning, when a piece of metal and piece of khaki were removed from the larger wound Antitetanic injection given and a second injection next day at Boulogne

On July 10th, on admission to Milton Hill Hospital, Berk shire, the patient appeared in good health Examination of shoulder showed two unhealthy looking wounds on posterior aspect The upper and larger one, just behind and below the acromion, was a superficial granulating area *about* an inch across The lower wound, over posterior fold of axilla penetrated deeper, X rays disclosed a piece of metal embedded in muscles at bottom of wound Both wounds were decidedly septic and were treated by hot fomentations and rest to the arm After 10 days the wounds showed little disposition to heal

On July 23rd patient complained of some stiffness in the shoulder Next day the whole arm from shoulder to wrist was in a state of tonic rigidity, and acutely flexed at elbow, no actual pain when arm was kept at rest, no painful spasms as yet, uneasiness in throat and right side of neck, and difficulty in swallowing food, pulse and temperature normal In the afternoon Sir William Osler saw him and made the following note No fever, patient complains a *little of pain in the epigastrium* and back and right shoulder The arm is flexed at the elbow, muscles stand out prominently and feel rigid Patient can flex and extend the fingers, but cannot extend the arm, forcible extension does not hurt him Pectoral muscles are not involved, *deltoid feels stiff* Patient cannot lift his head off the pillow He has occasional spasms of back and neck and arm with great pain He opens his mouth fairly well '

By evening the paroxysms had increased in frequency and severity, as also in area involved The muscles *of* whole right side of body except those of the leg were in a state of tense rigidity the abdominal wall was retracted and hard as a board, the left side of the body, except the left side of the abdominal wall, was unaffected Jaw clenched, head turned to right side Painful paroxysms, affecting *only the* right side, were brought on by any attempt at movement

By lumbar puncture 6 drachms of cerebro spinal fluid[1] were drawn off and 2000 U S A. *units of tetanus* antitoxin injected into spinal canal, 2000 units also given intra muscularly, chloretone gr xxx per rectum

July 25th Patient slept at intervals during the night, but when awake suffered much from sickness and pain in head and legs, *very profuse perspiration* Although the arm and right side of body generally remained rigid, the tetanic spasms did not increase in severity during the night Another injection of chloretone, gr xxx., per rectum and antitoxin, 2000 units, intramuscularly

On July 27th rigidity of right side and *flexure of* arm remained the same, the muscles of back of neck and posterior fold of axilla being specially hard, abdominal wall *tensely contracted and very tender to touch* The jaw could be opened but very slightly, "risus" well marked. The arm could be forcibly extended to a considerable extent without pain, but on relaxing it it returned to its flexed position, and this was immediately followed by a painful spasm involving the whole right side Even the leg was then thrust out as in cramp, but the foot appeared unaffected Patient complained of sore throat and severe *pain in* epi gastrium Retention of urine had been experienced, but catheter not required Antitoxin 2000 units intramuscularly *Chloretone gr* xxx per rectum

On July 29th rigidity the same, several spasms noted during the night, confined chiefly to right upper quadrant of body Jaw immovably fixed, feeding difficult Only liquids could be taken, and the act of swallowing was very painful Masses of tough dark phlegm formed in the throat were got rid of with extreme difficulty Nutrient enemata commenced Patient still lay with head turned to right side, mouth also drawn a little to the right, and eyes sometimes involuntarily rolled to that side, tongue bitten during sleep

On July 31st the general condition was much the same A notable feature was that the hand and fingers had been quite freely movable all along Neither were they affected during the paroxysms of spasm

On August 1st, except that abdominal muscles were still very *hard* and tender, the rigidity of the right side appeared to be relaxing The head could be moved a little from side to side but could not be raised Teeth firmly clenched but separated a little during sleep Painful spasms were still excited on small provocation

On August 5th the general rigidity of the arm and forearm, and the tendency to attacks of spasm, were gradually becoming less pronounced The jaws could be opened about half an inch, but the idea of solid food was dreaded The patient was seen by Sir David Ferrier, who observed

There is slight transitory ankle clonus in the right foot, no Babinski reaction, knee jerk slightly exaggerated The movements of the proximal muscles of the right limbs are involved in spasm, whilst the distal muscles (hand and foot muscles) are not affected The abdominal muscles are very *rigid There is a certain amount of spasm of the thoracic* muscles, but the expansion of the chest is found on measure ment to be about normal The platysma trapezius, and sternomastoid on right side are only slightly rigid The deltoid and biceps are very hard The arm is firmly flexed *at the elbow It lies across the chest and cannot be* voluntarily moved Forced extension immediately produces spasm "

On August 6th there was severe abdominal pain, mostly on left side On the 7th this pain extended down left leg which was much swollen from the knee downwards The internal saphenous vein was hard and very tender An attack of acute phlebitis, depending on a thrombus, probably of the iliac vein, had thus supervened For several days the swelling of the leg increased, and extended upwards to the groin, being accompanied by much pain, but only slight rise of temperature In a week the swelling began to subside, and in another week the phlebitis had practically gone, *slight* swelling and *discoloration of the leg persisted*, however, for several weeks

On August 13th, except for the muscles of right arm and forearm, which were still rigid, preventing full extension, the muscles of the right side were no longer in spasm They *felt abnormally soft and flabby* Patient was beginning to take solid food, but had a sensation as if his tongue were tied Painful spasms were still excited in the arm on attempts forcibly to extend it

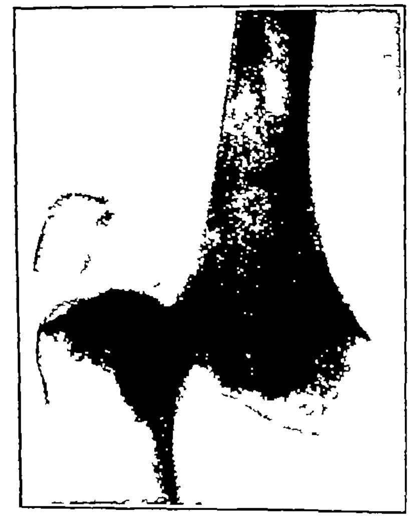
From this time steady progress was made, but in spite of *abundant nourishment and* exercise the patient's whole muscular system was for months deficient in tone He was easily fatigued, and complained of pains in the calves of the legs, and aching in the muscles generally, after even slight exertion For a long time the arm movement was very imperfect, and the elbow could not be voluntarily, or even by force, brought into a straight position, or raised above the head There remained a good deal of tenderness on pressure over the shoulder joint and along the line of the cervical plexus

With *regard* to the prophylactic effect of tetanus anti toxin it is rational to conclude that it will vary according to the amount of toxic material introduced into a wound, as well as to the dose of antitoxin given It is also a well established fact that the effect will be largely influenced by the route of administration the intrathecal route having been found by far the most efficacious Thus the result of an injection of the serum may be (*a*) Complete neutralisa tion of the poison and non appearance of the disease, (*b*) extension of the period of incubation and late appear ance of the disease (delayed tetanus), (*c*) limitation of the active and passive flexion, and the patella was freely movable On testing for abnormal mobility a slight "give" was experienced in both lateral directions A calliper splint was provided and worn for six weeks Seven months from the time of the injury the man began light work His present condition (11 months after the accident) is as follows The knee joint is painless, and shows a range of 20 degrees of flexion, there is definite abnormal lateral mobility of the tibia on the femur this can be elicited by firm manipulation, but is not evident to the man during ordinary use of the limb The man is now working at his old employment as a labourer and is carrying out full duties with the exception of climbing ladders

---

[1] Cerebro-spinal fluid examined was found to contain a faint trace of albumin no sugar no cells, no deposit

FIG 2



J E dislocation of knee joint Backward and outward displacement of femur

In the two cases described above, as in all complete dislocations of the knee joint, total rupture of both crucial ligaments with extensive tearing of the capsule, must have occurred Under conservative treatment, prolonged over a sufficient period there is every chance of spontaneous repair of these torn structures This fact has been repeatedly emphasised by Robert Jones who has seen some extraordinarily good functional results in this type of injury, when continued fixation has been employed In several of the cases described by this author considerable degrees of motion have been preserved, enabling the individuals to return to full work involving kneeling or to indulge in active sports The results in my two cases have fallen short of this ideal

In the case of the young woman I am inclined to regard the period of fixation as too long, as she had gone home to the Midlands there was great delay and trouble in having her readmitted to the hospital, thus we lost valuable time It is possible that in the course of time there may be a certain degree of stretching of the fibrous mass which fills up the position formerly occupied by the crucial ligaments, with a consequent development of motion in the joint I have not considered it justifiable to attempt to gain mobility by the use of forcible passive movement, so in this case I look upon the result—viz, firm fibrous ankylosis—as likely to be permanent.

In the second case after four months' work, there has been a definite increase in the mobility of the injured knee but I do not anticipate further appreciable increase, as there is very stout resistance to flexion beyond 20 degrees The man is doing heavy work with comfort, and expresses himself as very satisfied with the result The accompanying radiograms are probably unique For their existence and for the notes of the cases on admission to the hospital I am indebted to my former house surgeons, Dr Booth and Dr von Mengershausen

THE OPERATIVE TREATMENT OF ABDOMINAL ANEURYSM

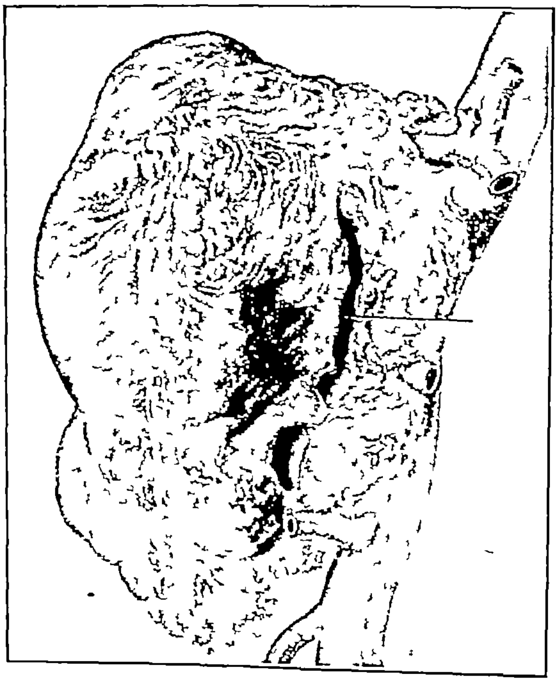
BY W I DE C WHEELER, F R C S IREL.,
HON MAJOR R A M C HON SURGEON TO THE FORCES IN IRELAND

FIVE years ago, at the annual meeting of the British Medical Association held in Birmingham,[1] I brought before the Association the details of two cases of abdominal aneurysm treated by operation A year later a third case came under my care, and, like the others, was treated by the introduction of wire into the sac I am now in a position to record the results of operation in the three cases, and in so doing hope to add some information to a subject which has engaged surgical attention for many years

It is noteworthy that every reported series of cases treated by operation contains a percentage of cures, but the earlier cases dating from the year 1865 showed a discouraging mortality Osler states that Nature occasionally cures a case Now and again the physician is able to effect a cure, but he had never seen such a case, and in a few instances he thinks that the surgeon prolongs life or even effects a complete cure Most of the cases mentioned by Osler lived from a few hours to six months after operation, one surviving three and a half years

The recognition of the fact that the introduction of a foreign body into an unhealthy area such as wire into an aneurysm, requires an aseptic technique of a very special kind, has rendered the results of recent operations more favourable In a case of fracture treated by the application of screws and plates accidental sepsis may be retrieved by the removal of the screws and plate but once the wire is introduced into the sac of an abdominal aneurysm it is past recall and the surgeon is unable to retrace his steps

FIG 1



Side view of aneurysm. The line marks the point of rupture (One-half natural size)

The use of Colt s apparatus[2] removes the danger caused by the advance of wire from the sac of the aneurysm into the aorta beyond At least six cases succumbed to this cause in the old days Rupture of the aorta or of a secondary aneurysmal sac may to some extent be obviated by the rigid application of antispecific treatment as it is now understood There is also the possibility of emboli being carried on the point To date we have had access to 97 *carriers of Entamœba histolytica* cysts invalided from France or Flanders as dysentery convalescents The results obtained by exami nation of the blood are shown in Table II —

---

[1] Brit Med Jour 1911 THE LANCET 1911 ii 607
THE LANCET 1903 ii 808

TABLE II —*Agglutination Tests in the Case of Amœbic Carriers from France*

Number of cases	97
Number of cases in which the blood agglutinated B Flexner	26
Number of cases in which the blood agglutinated B Shiga	7
Number of cases in which the blood failed to agglutinate either B Flexner or B Shiga	64

Of these 97 cases 66 had never been with any other than the B E F, nor had they at any time previous to the war visited a country in which amœbic dysentery is known to be endemic They must, then, have become carriers in France In 38 of these 66 cases a history of contact with likely sources of infection was obtainable

For sake of comparison it was decided to examine in a similar manner carriers of *Entamœba histolytica* cysts invalided from the Mediterranean area, with a few exceptions from Salonika The results obtained are set forth in Table III —

TABLE III —*Agglutination Tests in the Case of Amœbic Carriers from the Mediterranean*

Number of cases	98
Number of cases in which the blood agglutinated B Flexner	5
Number of cases in which the blood agglutinated B Shiga	28
Number of cases in which the blood failed to agglutinate either B Flexner or B Shiga	65

It will be noticed that the percentage of positive and negative agglutination tests is identical with that obtained in the cases invalided from France When, however, the cases with positive agglutination tests are considered it is found that some 78 per cent of the French cases are accounted for by the B Flexner, whilst conversely over 80 per cent of Mediterranean cases are accounted for by B Shiga Finally amœbic carriers admitted to the hospital from the Forces in India, Mesopotamia, and Egypt have been similarly examined The results are exposed in Table IV —

TABLE IV —*Agglutination Tests in the Case of Amœbic Carriers from India, Mesopotamia, or Egypt*

Number of cases	35
Number of cases in which the blood agglutinated B Flexner	1
Number of cases in which the blood agglutinated B Shiga	3
Number of cases in which the blood failed to agglutinate either B Flexner or B Shiga	31 (88 5%)

The experiments referred to above are, in our opinion, suggestive from several points of view For the reason, however, that they only form the beginning of a series of researches we do not propose, for the present, to go more deeply into matters than we have already done

One conclusion of practical import may, however, be emphasised It is highly important that careful protozoological as well as bacteriological and serological examinations be made in every case of dysentery coming under investigation A positive bacteriological or serological finding, for example does not preclude the necessity for a careful protozoological examination

In conclusion, it is a pleasant duty to acknowledge our indebtedness to Lieutenant-Colonel T H F Clarkson, R.A.M C, officer commanding Mont Dore Military Hospital, Bournemouth, for permission to publish this note and for whole hearted support and encouragement

---

LITERARY INTELLIGENCE —The fourth edition of Mr Comyns Berkeley's Handbook of Midwifery is announced for early publication by the house of Cassell It has been considerably expanded to meet the additional requirements of the Central Midwives Board and to render it suitable for obstetric dressers

TRAUMATIC DISLOCATION OF THE KNEE JOINT

A REPORT OF TWO CASES

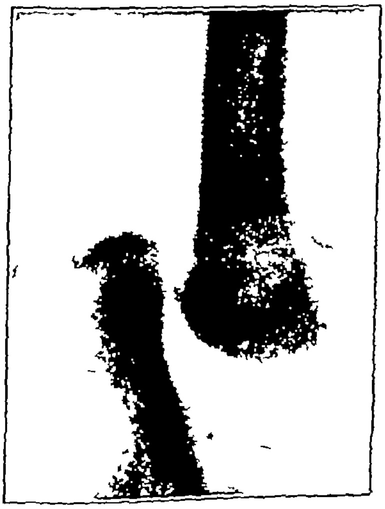
BY HARRY PLATT, M S LOND, F R C S ENG,
HONORARY SURGEON AND SURGEON IN CHARGE, ORTHOPÆDIC DEPARTMENT ANCOATS HOSPITAL, MANCHESTER CAPTAIN R A M C (T) 2ND WESTERN GENERAL HOSPITAL

(*From the Orthopædic Department, Ancoats Hospital*)

COMPLETE traumatic dislocation of the knee-joint is a condition seen so infrequently that it is well worth while recording all cases of this type During the last 18 months two individuals with this rare injury have been admitted to the Ancoats Hospital Manchester, under my care and I have had an opportunity of controlling the treatment in both cases and of observing the functional result obtained

CASE 1 —L S, a female aged 20, whilst crossing a field in the dark, slipped, caught her left foot in a hole, and fell over backwards on to her left side She was brought to hospital on Sept 17th, 1915, within an hour of the accident, a tentative diagnosis of fractured femur having been made by an outside doctor On examination the left knee-joint revealed an obvious complete dislocation, the femur being displaced backwards, the upper end of the tibia being abnormally prominent with a deep hollow above. The amount of effusion in and around the joint was strikingly small, and there were no signs of any circulatory obstruction in the limb A radiogram (Fig 1) was taken before reduction was attempted this latter manœuvre being accomplished with ease by Dr W S Booth, the senior house surgeon to the hospital The limb was then put up on a back splint, and after ten days' stay in hospital the patient was sent home to Wolverhampton, a plaster cast having been applied extending from the toes to the groin Five months later the patient was readmitted to hospital and the cast removed The injured joint was now absolutely stiff in the position of full extension, no motion could be elicited even though considerable force was exerted A radiogram showed atrophy of the cancellous tissue of the bone ends, but there was a clear cartilage line on both bones The girl began to walk on the limb, wearing a calliper splint for the first two months Her present condition (15 months after the accident) is as follows The knee joint is firmly ankylosed, the patella being adherent to the anterior surface of the femur The patient walks well without pain and is following her occupation

FIG 1



L S dislocation of knee-joint Backward displacement of femur no lateral displacement

CASE 2 —J E, a man aged 47 fell from the top of a ladder to the ground a distance of 12 feet his left knee striking a plank, the point of impact being localised to the inner side of the joint He was admitted to hospital on April 1st 1916 some 20 minutes after the accident The left knee showed all the signs of a complete dislocation, with the femur displaced backwards and slightly outwards There was a moderate effusion into the joint, but no evidence of vascular obstruction A skiagram (Fig 2) was taken before reduction by the senior house surgeon, Dr H M von Mengershausen Reduction, as in the first case, presented no difficulties At the end of a week the man left hospital with his leg in a plaster cast. This fixation was maintained for four months On removal of the plaster the joint allowed five degrees of mortem wounds, for the percentage of cases in which septicæmia resulted was very small The anaerobic organisms were found in great numbers in the damaged bone tissue, especially in sequestra and in fragments of detached bone, this lent support to the method of treatment adopted by Major Swan, especially in view of the fact that the organisms persisted for many months in their comparatively secluded positions He attached some importance to the preparatory course of mixed vaccines which had been employed Since early treatment was desirable he advocated the use of heterogeneous vaccines prepared from cultures grown on the blood of patients who had got well and sensitised with the corresponding antitoxins until an autogenous vaccine had been prepared

Colonel WARING agreed in the main with the contentions of Major Swan His experience had led him to prefer early excision and free drainage, with efficient flushing to primary incision and excision at a later date Speaking of the muscular power which might follow excision of joints, he recalled a case of a man whose elbow joint had been excised in pre aseptic days but who had subsequently been able to carry on his work as a blacksmith

Mr RAYMOND JOHNSON spoke of the unsatisfactory results from treatment by incision, drainage, and flushing alone in the early stages and thought that Major Swan had made out a case for his method which demanded for it a satisfactory trial It was desirable, he thought Major Swan would admit to excise the ends of all the bones entering into the joint whether all were damaged or not In two cases under his observation where this had not been done the results had not been good.

Dr HELEN CHAMBERS said that observations which she had made at the Women's Military Hospital, Endell street, had shown that irrigation by solutions into septic wounds only rendered the surface sterile when one of two solutions was used—eusol or Dakin's solution Even then the result was only temporary What was needed was some application the effect of which was continuous Such could only be applied in the form of a paste. The bismuth iodoform paste satisfied the condition and had proved very useful

Major SWAN, in his reply, agreed that excision of all the ends of bones was desirable *provided* that the gap produced was not unduly wide (wider than two fingers' breadth) He had not found any one solution of greatest value but favoured a change *from* one solution to another He was not convinced of the usefulness of bismuth iodoform paste, having met with failures where he had to remove it, and had found the surrounding tissues contained many organisms

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF OBSTETRICS

Pneumonia in the Puerperium —Backward Displacement of the Uterus

A MEETING of this section was held on March 2nd, Dr GIBBON FITZGIBBON, the President being in the chair

Mr SPENCER SHEILL read a paper on a case of Pneumonia in the Puerperium The patient developed a mammary abscess, which was opened on the eleventh day Up to the ninth day her temperature was normal After the operation double septic pneumonia set in from which she died six days later There was no evidence of septic infection elsewhere than the breast The principal point of interest was the origin of the pneumonia.

Dr R D PUREFOY said it appeared to him that the breast condition was a local evidence of a general septic condition, which developed with accelerated speed after the abscess was treated Rokitansky and McClintock had recorded cases of puerperal sepsis, attended with suppuration in the breast

Dr BETHEL SOLOMONS considered that the case was probably one of embolic pneumonia secondary to the mastitis He regretted that Mr Sheill had not attempted to obtain a culture from the mammary pus or from the uterus as an autogenous vaccine might have helped in treatment

Dr H C DRURY showed charts of patients who had developed pneumonia during pregnancy The prognosis was, he said favourable for the mother and bad for the child as premature labour often occurred Labour had a beneficial effect on the disease

Mr SHEILL, in reply, stated his belief that septic emboli from the breast caused the trouble, and that these were admitted to the circulation by the use of Bier's apparatus, which created such powerful suction as to rupture some small veins, and that when the pressure was released septic matter was drawn into these veins He suggested that suction treatment was fraught with danger in cases where the abscess did not freely communicate with the surface

Dr ALFRED SMITH read a paper on the Operative Treatment of fixed Backward Displacement of the Uterus

Reviews and Notices of Books.

Glaucoma A Handbook for the General Practitioner By ROBERT HENRY ELLIOT, M D Lond, F R C S Eng, Lieutenant-Colonel I M S (retired) London H K Lewis and Co, Limited 1917 Pp 60 Price 3*s* 6*d* net — Lieutenant-Colonel Elliot has written a short but clear account of glaucoma, excellently illustrated He deals successively with the anatomy of the parts concerned in glaucoma, the intraocular pressure, the pathological anatomy, causes, diagnosis, signs and symptoms, and treatment of the disease He has addressed the general practitioners, but whether these readers will find the help they require is in our opinion doubtful The book is written from the specialist's point of view, and insufficient guidance is given as to diagnosis, which is, after all, what the general practitioner wants For example, he should be instructed minutely as to the distinction between iritis and glaucoma yet the only reference to iritis in the whole book occupies less than three lines In spite of the usual warnings as to the use of mydriatics the author says, on p 51, "there are cases in which the bold use of atropine or of eserine, selected according to the exigencies of the individual case, may prove invaluable." The exigencies which demand the use of atropine are by no means precisely stated, and the general practitioner will gain little help from such statements Neither will he be much the wiser for brief accounts of all the modern operations for glaucoma, several of which have been practically abandoned in England We agree with nearly all that Lieutenent-Colonel Elliot says in his book, which none the less appears to us to fail somewhat in the object for which it was written

Collected Papers on Circulation and Respiration Second Series Clinical and Experimental. By Sir T LAUDER BRUNTON, Bart London Macmillan and Co 1916 Pp 719 Price 5*s* net.—Brunton did not live to see the completed publication of his collected papers on Circulation and Respiration This second volume is a large one, containing 68 articles with 256 illustrations covering a period from 1883 to 1915 The last article on Functional Diseases of the Arteries was published in our columns in July, 1915 Some of the articles, such as that 'On Posture and its Indications," are almost classical in their familiarity, all give evidence of Brunton's chiefest aim in life to leave therapeutics as a science, instead of merely an art as he found it This volume is not merely a monument of hard thinking, but also a token of the success of his aim

Minor Surgery and Bandaging (Heath and Pollard) For the Use of House Surgeons, Dressers and Junior Practitioners By H MORRISTON DAVIES M D, M C Cantab Sixteenth edition London J and A Churchill. 1917 Pp 476. Price 8*s* 6*d* — Three years ago this 55-year old manual was successfully remodelled with a view to modern requirements A chapter has now been added on the general principles of treatment of gunshot wounds of the limbs The author states in his preface that it would be impossible to deal generally with the whole subject of military surgery without materially altering the scope and character of the book We think that in the next edition this will have to be done as the surgical lessons of the war are not long to be kept in a water tight compartment, but will have their influence on every department of peaceful surgery

The Microscopy of Vegetable Foods By ANDREW I WINTON, Ph D with the collaboration of Dr JOSEF MOELLER and KATE BARBER WINTON Ph D Second edition With 635 illustrations London Chapman and Hall Limited, New York John Wiley and Sons, Inc 1916 Pp 701 Price 27*s* 6*d* net —The increasing number from the sac during, or after, the introduction of the wire, death from this cause, however, has been extremely rare

The results of my three cases are as follows —

In the first case of aneurysm of the aorta in the region of the cœliac axis, operated upon in August, 1910, a cage of 150 inches of Colt's wire was introduced At the time of operation the aneurysm was thin walled and seemed ready to burst The patient is still alive and well, at daily work in a brewery The aneurysm has consolidated and a loud systolic murmur present before operation has disappeared

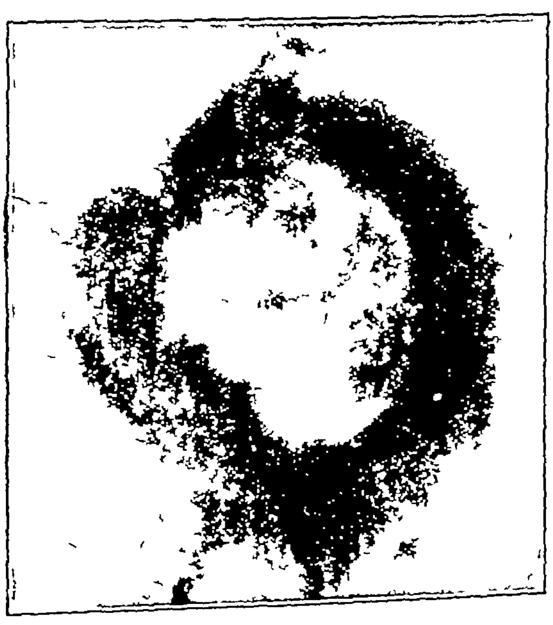
The second case, also reported upon in 1910, died in March, 1916, from rupture of the aneurysm, when acting as a stoker in the R N R on board a patrol trawler A wisp of 105 inches of wire was introduced in this case A complete post-mortem examination was obtained, the details of which are given below

The third case was operated upon in 1912 and died about a week after the introduction of the wire from rupture of the aneurysm following intestinal obstruction A gastro enterostomy was performed in this case as the aneurysm was obstructing the pylorus The loop of jejunum fixed to the stomach became strangulated by pressure between the abdominal wall and the aneurysm, the consequent vomiting led to rupture of the sac

In analysing these three cases the first man may be fairly said to be cured The operation was performed six years ago, at a time when the sac was large and thin walled At present the only remaining sign of an aneurysm is a hard mass which transmits the pulsation of the aorta to the abdominal wall The patient is in good health and performs a full day's work

The second case lived over five years, and died, while acting as a stoker on board a trawler, from rupture of the sac From the post-mortem examination it may be fairly claimed that this case was practically cured, and but for the fact that the man was occupied in one of the most strenuous occupations the greatly consolidated aneurysm might never have ruptured

FIG 2



X ray photograph showing Colt's wire within the sac.

No conclusions can be drawn from the result of Case 3, the rupture of the aneurysm after the introduction of the wire being obviously due to the vomiting of acute intestinal obstruction

I am indebted to Surgeon H E King Fretz, R N, for the following post-mortem examination and other notes on Case 2

The patient, aged 37 a stoker, R N R, on one of the patrol trawlers, was admitted into the Naval Hospital on March 12th, 1916 He complained of vomiting and severe shooting pain in the right lumbar region simulating renal colic There was tenderness in the region of the appendix and pain on deep inspiration He was sweating freely and in a state of collapse There was a large pulsating tumour which practically occupied the whole of his epigastric region, apparently an aneurysm of the abdominal aorta His temperature was 97° F, pulse 120, full and regular, systolic pressure 280 mm, diastolic pressure 120 mm. His urine showed a heavy deposit of urates and a trace of albumin There was an excellent scar to the left of the mid line 3 inches long, the result of operation five years ago A systolic bruit could be heard over the swelling, propagated all over the abdomen and down both femoral arteries There was a marked diastolic sound in the mitral area and a very accentuated second sound in the aorta Seven days after admission he died The swelling continued to pulsate long after respirations had ceased

At the autopsy it was found that there was a small leak, the hæmorrhage penetrated between the layers of the mesentery, separated them widely apart, and surrounded a large portion of the small intestine The right kidney was pushed forward Both kidneys and spleen were normal in size, the right kidney having small granular patches on the surface The heart was much enlarged Now for the aneurysm, I am not exaggerating when I say that the clot formed in it is as hard as a rock, the aneurysm itself is about the size of a full term fœtus' head It appears to me as if there is a secondary dilatation of the aorta below the main swelling and that is where the trouble arose'

I am also indebted to Surgeon King Fretz for the specimen which is faithfully illustrated in Fig 1, and for the X ray photograph showing the wire *in situ* (Fig 2)

It is noteworthy that all three cases presented themselves at hospital complaining of severe pain in the back, and that in none was there any erosion of the vertebræ It is possible that the intense pain in the back, common to cases of abdominal aneurysm may be due to the stretching of the highly sensitive posterior parietal peritoneum, which is also in these cases subject to a pull at every pulsation of the tumour

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE

Exhibition of Autochromes

A MEETING of this section was held on March 27th, Dr T D ACLAND being in the chair

Dr C R BOX and Mr WALTER EDMUNDS exhibited a series of autochromes illustrating the rashes of rubella, measles, scarlet fever, typhoid, cerebro-spinal fever, and pellagra in cases treated at the London Fever Hospital The autochromes were the products of a three colour process, the rays of light being transmitted through starch granules, coloured respectively green, orange, and violet, before coming into contact with the customary photographic emulsion This permitted a very faithful portrayal of the characteristic rashes The chief drawbacks to the method were the length of exposure necessary with daylight the intensity of the arc light required when daylight was not used the impossibility of reproduction, and, for demonstration purposes the short distance from the screen at which the images must be viewed to appreciate their details

SECTION OF SURGERY

Treatment of Severe Infected Gunshot Injuries of the Shoulder and Elbow Joints

A MEETING of this section was held on March 14th Colonel H J WARING being in the chair

Major R H. JOCELYN SWAN read a paper on the above subject, in which he advocated early excision of the joints with the object of obtaining mobility The paper is published in full in our present issue

Mr KENNETH GOADBY who had been collaborating with Major Swan, spoke from the bacteriological standpoint He showed by lantern slides of the pus the high degree of septicity of such wounds Besides ordinary pyogenic organisms anaerobes (*B perfringens* the bacillus of malignant œdema, *B Hibler IX*) were commonly present The streptococci did not seem to be as virulent as those found in civilian practice, such as in post-mortem wounds, for the percentage of cases in which septicæmia resulted was very small. The anaerobic organisms were found in great numbers in the damaged bone tissue, especially in sequestra and in fragments of detached bone, this lent support to the method of treatment adopted by Major Swan, especially in view of the fact that the organisms persisted for many months in their comparatively secluded positions He attached some importance to the preparatory course of mixed vaccines which had been employed Since early treatment was desirable he advocated the use of heterogeneous vaccines prepared from cultures grown on the blood of patients who had got well and sensitised with the corresponding antitoxins until an autogenous vaccine had been prepared

Colonel Waring agreed in the main with the contentions of Major Swan His experience had led him to prefer early excision and free drainage, with efficient flushing to primary incision and excision at a later date. Speaking of the muscular power which might follow excision of joints, he recalled a case of a man whose elbow joint had been excised in pre-aseptic days but who had subsequently been able to carry on his work as a blacksmith.

Mr Raymond Johnson spoke of the unsatisfactory results from treatment by incision drainage, and flushing alone in the early stages and thought that Major Swan had made out a case for his method which demanded for it a satisfactory trial It was desirable, he thought Major Swan would admit to excise the ends of all the bones entering into the joint whether all were damaged or not In two cases under his observation where this had not been done the results had not been good.

Dr Helen Chambers said that observations which she had made at the Women's Military Hospital, Endell street, had shown that irrigation by solutions into septic wounds only rendered the surface sterile when one of two solutions was used—eusol or Dakin's solution Even then the result was only temporary What was needed was some application the effect of which was continuous Such could only be applied in the form of a paste The bismuth iodoform paste satisfied the condition and had proved very useful

Major Swan in his reply, agreed that excision of all the ends of bones was desirable provided that the gap produced was not unduly wide (wider than two fingers' breadth) He had not found any one solution of greatest value but favoured a change from one solution to another He was not convinced of the usefulness of bismuth iodoform paste, having met with failures where he had to remove it, and had found the surrounding tissues contained many organisms

Pneumonia in the Puerperium —Backward Displacement of the Uterus

A meeting of this section was held on March 2nd, Dr Gibbon FitzGibbon the President being in the chair

Mr Spencer Sheill read a paper on a case of Pneumonia in the Puerperium The patient developed a mammary abscess, which was opened on the eleventh day Up to the ninth day her temperature was normal After the operation double septic pneumonia set in from which she died six days later There was no evidence of septic infection elsewhere than the breast. The principal point of interest was the origin of the pneumonia.

Dr R D Purefoy said it appeared to him that the breast condition was a local evidence of a general septic condition which developed with accelerated speed after the abscess was treated Rokitansky and McClintock had recorded cases of puerperal sepsis, attended with suppuration in the breast

Dr Bethel Solomons considered that the case was probably one of embolic pneumonia secondary to the mastitis He regretted that Mr Sheill had not attempted to obtain a culture from the mammary pus or from the uterus as an autogenous vaccine might have helped in treatment

Dr H C Drury showed charts of patients who had developed pneumonia during pregnancy The prognosis was he said favourable for the mother and bad for the child as premature labour often occurred Labour had a beneficial effect on the disease

Mr Sheill, in reply, stated his belief that septic emboli from the breast caused the trouble, and that these were admitted to the circulation by the use of Bier's apparatus, which created such powerful suction as to rupture some small veins, and that when the pressure was released septic matter was drawn into these veins He suggested that suction treatment was fraught with danger in cases where the abscess did not freely communicate with the surface

Dr Alfred Smith read a paper on the Operative Treatment of fixed Backward Displacement of the Uterus

Reviews and Notices of Books.

Glaucoma A Handbook for the General Practitioner By Robert Henry Elliot, M D Lond, F R C S Eng, Lieutenant-Colonel I M S (retired) London H K Lewis and Co, Limited 1917 Pp 60 Price 3*s* 6*d* net —Lieutenant-Colonel Elliot has written a short but clear account of glaucoma, excellently illustrated He deals successively with the anatomy of the parts concerned in glaucoma, the intraocular pressure, the pathological anatomy, causes diagnosis, signs and symptoms and treatment of the disease He has addressed the general practitioners, but whether these readers will find the help they require is in our opinion doubtful The book is written from the specialist's point of view, and insufficient guidance is given as to diagnosis, which is, after all, what the general practitioner wants For example, he should be instructed minutely as to the distinction between iritis and glaucoma yet the only reference to iritis in the whole book occupies less than three lines In spite of the usual warnings as to the use of mydriatics the author says, on p 51, "there are cases in which the bold use of atropine or of eserine, selected according to the exigencies of the individual case, may prove invaluable.' The exigencies which demand the use of atropine are by no means precisely stated and the general practitioner will gain little help from such statements Neither will he be much the wiser for brief accounts of all the modern operations for glaucoma, several of which have been practically abandoned in England We agree with nearly all that Lieutenent-Colonel Elliot says in his book, which none the less appears to us to fail somewhat in the object for which it was written

Collected Papers on Circulation and Respiration Second Series Clinical and Experimental. By Sir T Lauder Brunton, Bart London Macmillan and Co 1916 Pp 719 Price 5*s* net.—Brunton did not live to see the completed publication of his collected papers on Circulation and Respiration This second volume is a large one, containing 68 articles with 256 illustrations covering a period from 1883 to 1915 The last article on Functional Diseases of the Arteries was published in our columns in July, 1915 Some of the articles, such as that 'On Posture and its Indications,' are almost classical in their familiarity, all give evidence of Brunton's chiefest aim in life to leave therapeutics as a science, instead of merely an art as he found it This volume is not merely a monument of hard thinking, but also a token of the success of his aim

Minor Surgery and Bandaging (Heath and Pollard) For the Use of House Surgeons Dressers and Junior Practitioners By H Morriston Davies M D, M C Cantab Sixteenth edition London J and A Churchill. 1917 Pp 476 Price 8*s* 6*d* —Three years ago this 55-year old manual was successfully remodelled with a view to modern requirements A chapter has now been added on the general principles of treatment of gunshot wounds of the limbs The author states in his preface that it would be impossible to deal generally with the whole subject of military surgery without materially altering the scope and character of the book We think that in the next edition this will have to be done as the surgical lessons of the war are not long to be kept in a water tight compartment but will have their influence on every department of peaceful surgery

The Microscopy of Vegetable Foods By Andrew L Winton Ph D, with the collaboration of Dr Josef Moeller and Kate Barber Winton, Ph D Second edition With 635 illustrations London Chapman and Hall, Limited, New York John Wiley and Sons Inc 1916 Pp 701. Price 27*s* 6*d* net —The increasing number of publications on the microscopy of vegetable foods may be welcomed as likely to be helpful in the detection of fraud The pioneer work in this direction was largely done in THE LANCET Analytical Commission which in the "seventies" exposed, by means oftentimes of the microscope alone, the extent to which the adulteration of foods was then practised This exposure subsequently led to legislative steps being taken which are now embodied in the present Sale of Food and Drugs Acts in this country The authors of this large volume have taken considerable pains to produce a work of value and its text and the illustrations will give assistance to analysts and others in this country as well as in the United States The chapters on histology and morphology are the best features of the book, but now and again the illustrations are not as well drawn as they might be, and the context here and there is meagre and scrappy A good deal of ground is, however, covered, and the copious references to literature serve a useful purpose

X Rays By G W C KAYE M A, D Sc Second edition London Longmans, Green and Co 1917 Pp 285 Price 9s —We welcomed the appearance of this authoritative book when it first appeared three years ago The present edition has been revised by the author, as far as his military duties permit, up to the middle of 1916 A chapter on X ray equipment and technique has been added by Mr W F Higgins Accurate in presentation and attractive in style the book will continue to achieve its purpose

Sewerage The Designing, Construction and Maintenance of Sewerage Systems By A PRESCOTT FOLWELL Seventh edition, revised and enlarged London Chapman and Hall, Limited, New York John Wiley and Sons, Inc 1916 Pp 540 Price 12s 6d net —This book illustrates with a wealth of detail the way in which the problems of sewage engineering and disposal are being attacked in the United States It deals fully with the important question of practical sewer construction, and is divided into four parts, the first devoted to designing, the second to construction, the third to maintenance, and the fourth to disposal The question of utilisation does not appear to have come any nearer a practical issue in the United States than it has done in this country In fact, the writer says, speaking of chemical treatment and precipitation methods, "no method has yet been found by which the fertilising values of sludge can be made use of to sufficient advantage to induce farmers to use it even when it is given them free of cost, except in a few cases" The author then refers to the sludge ships which convey the sludge from the London sewage works 50 miles out to sea and dump it there The book will be valued by engineers engaged in this important branch of sanitary science and to some extent by chemists, the appendix containing a useful account of the analytical methods employed in testing sewage, and a short bacteriological section on the examination of effluents in regard to bacterial reduction

Essentials of Physiology By F A BAINBRIDGE and J ACWORTH MENZIES Second edition With 173 illustrations London Longmans Green, and Co 1916 Pp 478 Price 12s 6d net —This is the second edition of a companion volume to the "Essentials of Histology" (Schäfer) of "Morbid Histology" (Grünbaum), and of "Chemical Physiology" (Halliburton), and maintains the high standard of the series Although avowedly written with the primary object of meeting the requirements of the medical student preparing for a pass examination, it is in no sense a cram book and no one can read it carefully without gaining a useful insight into the whole field of modern physiology The book is indeed remarkable for its even and adequate treatment of all parts of the subject, and for the average high standard of the illustrations which are drawn from many sources The text is clear and interesting to read

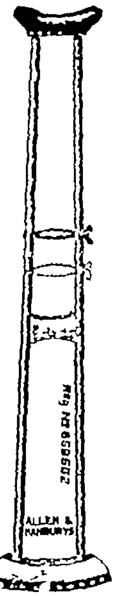
Some Modern Methods of Ventilation, with Special Reference to Public Buildings By R GRIERSON With illustrations, charts, and tables London Constable and Co, Limited 1916 Pp 187 Price 8s 6d net —While the author s point of view is largely the engineering one it is clear that he keeps in mind the physiological considerations on which methods of ventilation must be based if they are to give satisfactory results. Thus he speaks of the conditioning" of the air which is the most important factor in the situation and he accepts the dictum of Dr Leonard Hill that the physical effect upon the skin is the supremely important thing, not its chemical effect This view has now received general acceptance, and so the conditioning of the air as regards its physical state—e g , humidity, movement equable temperature freedom from dust, and so forth—is much more to the point than keeping down a carbonic acid gas contamination As the author observes, "Even more disconcerting to the old school of hygienists must be the growing practice of American engineers to arrange for recirculation of the air many times in succession," and the washing plant is left to maintain the air of the ventilated space in a pure condition This system it is added effects considerable economy in the fuel bill in cold weather, and we may take it that the authorities are satisfied that the air so treated is wholesome The book contains much useful information on standards of ventilation, design of ducts selection of fans washers and heaters specifications, test forms, and specimen schedules for designers, which will be consulted with advantage by those approaching these questions from a practical and rational point of view

A Hausa Botanical Vocabulary By JOHN M DALZIEL, M D B Sc Edin, D T M London T Fisher Unwin Limited 1917 Pp 119 Price 6s 6d net —The author of this useful compilation is a member of the West African Medical Staff, and has carefully utilised his opportunities The book is more than a vocabulary, and many descriptions of plants are given under their native names Under *dawa*, Guinea corn or great millet, are described some two dozen varieties of a food which the Hausa eats in the form of porridge, and to which he attributes special strength giving properties. The medicinal plants include a small field herb of the order *Polygalaceæ, sa hankali dako*, which is used in syphilis on the ground of its local reputation At the end of the book is given an index of genera and of popular names

New Inventions

AN IMPROVED CRUTCH

ANY improvement in the construction of crutches will no doubt be welcomed at the present time A crutch made of the ordinary ash sticks is shown in the diagram fixed at the lower end into a piece of hard wood curved at the base and shod with rubber (which I shall call the roller) and screwed to a block fixed below the handle The handle is fixed by a bolt and fly nut and can be adjusted to suit any length of arm The head is of the bridge type, the webbing stretched across being tubular and stuffed with horse-hair Attention may be drawn to the use of the roller at the foot, by which the rate of progression is materially increased and the pressure on the axilla is reduced As compared with the ordinary type of crutch the pace is increased at each step by the length of the arc of the circle taken by the roller This arc has been fixed at about 11 inches or less as being easily accommodated in railway trains omnibuses, and other places where space is important The most serviceable curve is the arc of a circle having a radius of 2 or 3 ft An important feature is the reduction in the tendency to skid on slippery surfaces



The new crutch has its defects it cannot be shortened so easily for use by a smaller man, it is heavier than the ordinary form of crutch and it is a little more costly to produce The extra weight is probably the only defect which will not in time be remedied and even this is largely compensated by the improvement in the balance which renders it more easily controlled

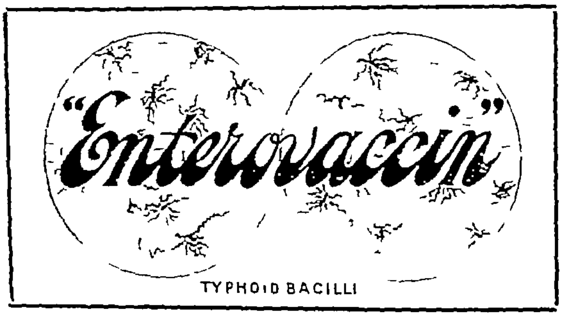
INOCULATION BY THE GASTRO-INTESTINAL TRACT IN PRACTICAL THERAPY.

From Papers read before the Therapeutical Society of Paris and the Academy of Sciences, Paris
By M Auguste Lumiere and by Messrs Lumiere and Chevrotier, Dr J P Dubarry, Prof A Chauveau

ANTITYPHOID



The results of **4000** applications of **Enterovaccin** carried out by approximately 200 Doctors are as follows

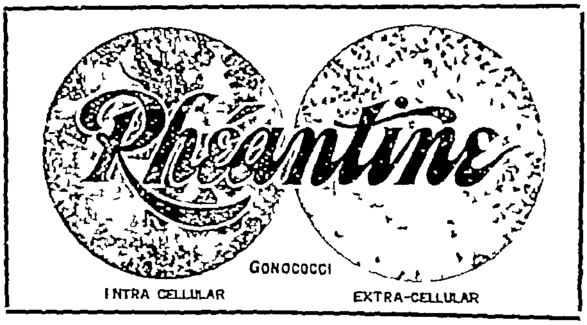
1 **No one** who has been treated with **Enterovaccin** has been attacked by typhoid fever

2 This method of immunisation is without risk

3 There is no contra indication

Enterovaccin is put up in hermetically sealed tins containing 28 spherules, sufficient for a complete treatment (one week) Each spherule contains per milligramme
300 millions Eberth bacilli 180 millions coli bacilli
120 millions paratyphoid bacilli

ANTIGONOCOCCIC



The clinical reports given by various Doctors show that **Rheantine** gives highly satisfactory results, both in acute and chronic forms of Gonorrhœa and also in the various infectious complications due to Neisser's bacillus

Rhéantine is put up in hermetically sealed tins containing 28 spherules

Each spherule contains approximately 50 millions of bacilli derived from 24 different stocks

Rheantine is therefore a strongly polyvalent vaccine

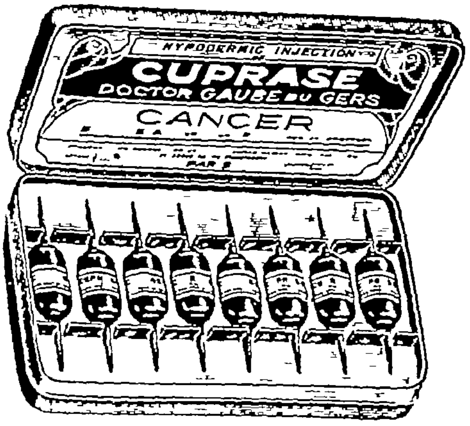
CUPRASE

For the Medical Treatment of CANCER.

Extract from Proceedings of the Royal Society of Medicine February 1913 —

Dr George Herschell, comparing electric and chemical colloid copper stated Chemical colloid appears to give the best results In the following cases chemically prepared colloid was used. Experimentally it has been proved: (1) That particles of colloid copper can be demonstrated in the granulations of cancerous growths after two or three injections of the colloid and clinically (2) There is invariably great relief from pain (3) Appetite and strength return and the patient puts on flesh; (4) There is in many cases a diminution in the size of the tumour (5) The injections are absolutely non-toxic, although in many cases an inflammatory reaction is manifested in the cancerous growths

As regards my own personal experience in the use of this method of treatment In addition to my own cases I have had an opportunity of observing the effects in the practice of some of my medical friends and in nearly all cases the progress of the disease appeared to be arrested"



CUPRASE is a Colloidal Copper hydroxide which is obtained chemically by the reduction of Salts of Copper in the presence of Albumosic Acid

This treatment has passed far beyond the experimental stage The numerous clinical reports from Doctors of repute in various countries give cases of a great variety In all of these **pain has been eliminated**, and in a good percentage **cures are claimed**, and in no instance **any undesirable effects**

Radiation in Malignant Disease

As old diseases are abolished or brought under control, new ones arise or new aspects of disease which were previously overlooked But cancer remains with us in spite of half a century of special hospitals and many years of intensive research, and the new Ministry of Public Health when instituted will find no task of greater difficulty or importance than to deal with malignant disease in all its forms Recent work with radium and the X rays in cases of malignant growth has begun to raise some hopes of a possible solution in this direction That we have in these sources of radiation a powerful ally in the war against malignant disease is now very generally admitted, but it cannot be said that it is being employed as yet to an extent justified by our present knowledge The reports and the paper by Captain A. A RUSSELL GREEN published elsewhere in this issue will serve to call attention to what is now actually being achieved, and a careful examination of the results attained by the workers in Edinburgh, Manchester, and Birmingham must, we think, go far to convince even the most sceptical of the value of the methods employed

The site of the growth naturally has a material influence on the treatment It is more or less an axiom among radiologists that the more superficial the lesion the more likely is it to be benefited by any form of radiation, and the high percentage of successful results in the treatment of rodent ulcer illustrates this clearly Difficulties increase in direct proportion to the depth to which the disease has invaded, the deeper structures, and modifications in technique are required on this account A study of the cases given in the reports from Edinburgh and Manchester especially shows that some measure of success has attended the efforts to overcome these difficulties The burying within the growth of tubes containing either radium or its emanation has produced excellent results, and this method holds out possibilities of permanence, since the base of the growth, from which metastasis arises, is attacked concurrently with its more superficial parts A further and a logical application of the principle here involved would indicate the removal of the more superficial parts of a malignant growth in order that the base may be more efficiently attacked The remarkable control of the X rays and radium over fungation removes the surgeon's most serious objection to operating under these circumstances, and is a further argument for a still closer coöperation between the surgeon and the radiologist than exists at present

The choice between radium and the X rays in dealing with cases of malignant disease is still in the stage of discussion, and it is doubtful if any good purpose could be served by advocating one at the expense of the other Each has its advantages as well as its disadvantages, and they have much in common The difficulty of obtaining radium in any quantity makes it rare, but its scarcity is compensated for largely by the constancy of its output—a condition that has greatly facilitated the development of radium therapy In contrast with the irregularity of the output from the X ray tube radium itself gives us a profuse supply of radiation easily and cheaply obtained This drawback to the use of X rays is, however, materially reduced in the latest form of tube construction Indeed, as a result of the introduction of the Coolidge tube it is not impossible that X ray therapeutics will undergo very considerable modifications Whichever method, however, is being practised, certain points have already emerged with more or less certainty, and the most important of these is the danger of delay Every day's delay diminishes the patient's chances of complete recovery, and this principle applies particularly to operable cases However favourable a case may appear, no surgeon can be sure that he has removed every trace of malignancy, or, indeed, that he himself has not scattered malignant cells over the field of operation Nothing should be left to chance, and as prophylactic radiation involves no necessity for disturbing the dressings or the patient, it should be commenced the day after operation. Another important matter of general agreement is that within reasonable limits long applications are preferable to short ones Perseverance, too, is a scarcely less powerful factor for success Many patients needlessly throw away months or years of useful and comfortable existence through failure to follow the advice that is given them In the light of the experience hitherto gained it is not too much to say that a good case has been made out for the use of some form of radiation in the great majority of malignant cases, and that its more general employment will have a favourable influence on their prognosis

◆

The Departmental Committee on Approved Societies and National Insurance

THE Departmental Committee which has had the finance of Approved Societies under its consideration in connexion with the part played by them in National Insurance issued an Interim Report in May and a Further Report in October, 1916, bringing its labours to a conclusion with a Final Report in February of the present year The Committee was asked by the terms of its reference, it will be remembered, to report upon any amendments in the financial scheme of the National Insurance Acts which experience of the administration of sickness, disablement, and maternity benefits might suggest to be desirable The amendments to be considered would, it was thought, necessarily be within the limits of contributions and benefits as they now stand and apart from further grants by the Exchequer although last week's resolution proposed by Mr KINGSLEY WOOD, a member of the National Insurance Advisory Committee, at a conference of Approved Societies, foreshadowed a substantial increase in maternity benefit as part of the expected infant welfare legislation. Further, the Committee was asked to make recommendations as to how far amendment of the National Insurance Acts and of the regulations made under them might simplify the work of the Societies and reduce its cost without detriment to the interest of the insured. The subject of the inquiry was therefore strictly limited to criticism, and to proposals having for their object the effecting of improvement under existing conditions or under conditions not radically altered, in matters connected with the finance and administration of Approved Societies.

In the two reports issued last year the Committee dealt with a variety of subjects intimately affecting Approved Societies and their finances, and suggested means whereby it seemed that a substantial measure of simplification in the machinery of the Acts and regulations might be secured. It was of the opinion, as stated in the report issued in October, 1916, that in the circumstances in which the Approved Societies were called upon to take part in National Insurance it would be neither fair nor reasonable to expect in the earliest youth of a newly devised system a simplicity and smoothness of working equal to that already established by the Friendly Societies after long experience in the conduct of their usual affairs, and it was predicted that whatever changes might be brought about as the result of experience, compulsory insurance upon the lines with which we are now becoming familiar must necessarily remain a highly complicated and intricate part of our social machinery. The report neither supported the views of those who complain that the Acts are too cumbrous and complex in character, nor did it express any expectation that its own deliberations would have as a result the cessation of complaints along the familiar and often reasonable lines. Those interested in the aspects of State insurance which present themselves to, and concern the Societies will, of course, study the reports as published. If they are technical they are carefully confined to elucidating the essential features of the matters dealt with, which are not always those which concern the medical profession as a whole, closely associated as that profession is with the working of National Insurance. The question of paying sickness and disablement benefit in respect of illness due to venereal diseases is, however, one matter in which the medical profession is deeply interested, as the stewards of the public health of the country rather than in the rôle of pathologists. The Committee recommends in its Final Report that, having regard to the danger to the community in the case of the person affected by venereal disease, Societies ought so to alter their rules as to enable benefits to be paid to a class of sick and disabled persons who hitherto have been excluded from them. The suggestion has everything to commend it, as is reflected in the opinion of all intelligent laymen. The sick person of the class which depends upon a Friendly Society for maintenance when wages cease on account of inability to work has a better chance of recovery when he is able to draw a weekly sum for his sustenance than he has if cessation of work means complete loss of income. He is also more likely, if he can draw sickness benefit without hindrance or comment and as a matter of right, to take effective steps towards regaining health in the early stages of illness. His recovery will remove a source of danger to other members of the community, and the prevention, or, failing this, the prompt treatment of his disease, is a matter now rightly recognised as one of national importance. At the same time, the alteration of the rules of a body of contributors to a common fund, in order to allow payments to be made to a class which was expressly excluded from participation in that fund when those contributors agreed to subscribe to it, presents some difficulty. The objections of those who will oppose any such change as that indicated will not necessarily depend upon sentiment or prejudice due to the association of venereal diseases with avoidable acts of immorality. They will be founded upon the entry of subscribers into a contract under conditions which it is proposed to alter to their detriment, a possible compensation being offered to them dependent upon the acquisition of a disease from which they may see no prospect of suffering. How far the opportunity to benefit the community by helping to diminish the prevalence of venereal diseases may appeal to persons thus situated will be tested if the recommendation of the Departmental Committee is sought to be adopted in any particular society, but the objectors will certainly occupy a strong position. Another question of equal or greater importance, financially and otherwise, to the Societies and their members is that of the payment of sickness and disablement benefit in the case of tuberculous disease during the period of after care. As to this the Committee refers to the existence of a national scheme, liberally assisted out of public funds, for the treatment of the whole community, including the uninsured and the insured. In view of this, the Committee did not feel justified in asking that the Societies should undertake a fresh burden. They had it in their power to render material assistance and to develop their policy so as to facilitate the promotion of useful experiments in "the wider field of public health," and beyond this they should not be asked to go. A third question, connected with the public health side of National Insurance, relates to inquiries into the causes of excessive sickness. As to this, the Committee pointed to the examples before it of the segregation of insured persons into societies of distinctive occupational hazard, and advised that the Insurance Commissioners, before any inquiry of the kind referred to was held, should satisfy themselves that a *prima facie* case for holding it had been made out.

With reference to the Further Report of the Committee made last October, we are reminded, while dealing with the Final Report, that the former contained a useful recommendation affecting hospitals and the duties of Approved Societies towards them in respect of payments The bulk of the Further Report, as we have said, was concerned with finance, and was of interest mainly to the Societies themselves, but the recommendation referred to dealt with contributors who are hospital in patients, and to the inability of Approved Societies to pay benefit to any member for his own direct personal benefit while an inmate of an institution The Further Report of the Committee advised that payment should be made to the dependents, if any, of a patient in a hospital or institution if he should so desire, and that in the case of a patient without dependents money otherwise due to him should, on his authorisation and at the discretion of his society,

> (a) Be utilised, in whole or in part, to defray any expenses otherwise than in respect of treatment or maintenance, for which he may be, or become, liable while he is in the institution, or so far as not so utilised, (b) be paid over to the authorities of the institution (not being a Poor law institution, or other institution maintained out of public funds) under an agreement entered into by his society, either generally or in the particular case

This would appear to render the contribution of an Approved Society to a hospital in respect of a particular patient dependent upon a combination of circumstances which would limit such payment to comparatively few occasions Contributions to Insurance Committees in respect of tuberculous patients treated in sanatoriums, also dealt with in the Further Report, are on a somewhat different basis The Committee here took the view, laid before it by some of the witnesses, that money so paid would better be devoted to helping the patient to recover complete health after discharge from the sanatorium The three reports taken together constitute an interesting document, the very limitations of which, due to restrictions of the reference made to it, serve to remind us of the impossibility of dealing effectively and upon a large scale with many of the problems of National Insurance before war is over Sir E CORNWALL doubtless had this difficulty in mind when he stated in the House of Commons last Monday his intention of making the Advisory Committee to the Insurance Commissioners a more workmanlike body by reducing its numbers from 168 to 30, and his proposal to appoint a small separate medical advisory committee is also a step in the right direction

---

DONATIONS AND BEQUESTS —By the will of the late Mr Francis Reckitt, of Beaconsfield, Bucks, the testator bequeathed £5000 each to the Great Northern Central Hospital, for their Convalescent Home and Dr Barnardo's Homes, £2000 to the King Edward's Hospital Fund, £1000 each to the Royal Hospital for Incurables, Putney, the Mount Vernon Hospital for Consumption and Diseases of the Chest Hampstead the Hull Royal Infirmary, and the Hull and East Riding Convalescent Home £500 each to the Hull Children's Hospital and the Cancer Hospital Brompton — The late Miss Caroline Emma Chretien has left by will the proceeds of the sale of Nelson House, Bexley Heath, to Bexley Cottage Hospital for an enlargement of the hospital to be known as " the Chretien Wing or Ward " and from the proceeds of sale of her other real estate legacies to the Royal Blind Pension Society and Poplar Hospital for Accidents Under the same will the London Hospital will receive Consols and stock of the value of nearly £5000

Annotations.

"Ne quid nimis"

MODERN CARDIOLOGY

IT is probable that the treatment of heart disorders can show a more substantial advance during the last 20 years than has been witnessed in any branch of our science since Laennec revolutionised our knowledge of thoracic disease a hundred years ago The contributing factors to this chapter in clinical medicine, which has been ably reviewed by Dr G A Sutherland in the Lumleian lectures this year, are to be traced, not only to the improved instrumental methods of examination of the heart, but particularly to the newer conceptions and clinical ideas which these methods have engendered For a long time it happened that our knowledge of the physiology of the circulation advanced in the laboratory, while the practical application of that knowledge remained very limited Even the introduction of the earlier graphic methods failed to realise the hopes which were founded on them A certain scepticism was aroused as to their value at the bedside, and this attitude extended at first to the later polygraphic methods of Sir James Mackenzie But the conditions were entirely different when Sir James Mackenzie's work began to attract the thoughtful attention of clinicians Gaskell had by this time established the coördinating factors of auricular and ventricular action Mackenzie perfected the means of clinically studying their respective actions, and, advancing along these lines, recognised that irregularity of the heart's action may not only be a matter of academic interest but might offer the key to the whole clinical course and character of many cardiac conditions There had been evolved, in fact, a living pathology of the heart Discovery followed discovery in quick succession, culminating in the final recognition of that most important condition auricular fibrillation The story of that condition—how it came to be identified and how its practical significance, and, above all, its response to treatment were verified—forms one of the most satisfactory chapters in clinical medicine, and was effectively detailed in our columns by Dr Sutherland Criticism will naturally not be wanting when some of these newer conceptions run counter to the teachings of the past, and Dr F J Smith finds that Dr Sutherland's exposition of modern cardiology defaults in not doing proper justice to the teachings, and especially the therapeutic successes, of such leaders of medicine as Gawen Sutton and Andrew Clark. We think Dr Smith, while rightly standing out against what he considers slight of the labours of past teachers, has not appreciated the real situation There need be no quarrel with the older school, no lack of reverence and respect for those past masters to whom we owe so much It is the manner in which their views have been distorted by subsequent teachers which, we imagine, falls mainly under Dr Sutherland's condemnation Newer methods have certainly widened our views of heart disease, but in doing so they have also induced an even greater sense of our ignorance than was perhaps felt by some of the earlier teachers to whom cardiac pathology must have seemed a simpler affair than it is to day More over, if the upshot of modern learning is to confirm previous routine a great advance has been made—the advance from empiric routine, with its risks of misapprehension, to scientific procedure with its sure basis for application and modification We do not find, therefore, Dr Sutherland's lectures lacking in respect for anything that is vital in the teachings of his predecessors, and while mere theory finds small space in his lectures, cardiac therapeutics, as far as they are represented in the employment of digitalis, receives the careful attention which it merits, and we think that many of the older clinicians, had they been present at the lectures, would have been gratified to find their intuitions confirmed by later physiological research Heart block is now found to be a far from rare clinical condition, and other arrhythmias have their true place and significance in pathology All this work has come to stay But if one thing stands out more particularly revealed by these new methods it is this the essential importance of clinical subjective symptoms This later work has only heightened the significance of the patient's own feelings, his "field of cardiac response" Instrumental methods can never replace clinical bedside observation, and it is to this latter field that these Lumleian lectures are so fittingly devoted And while we respect and have every sympathy with Dr Smith s attitude in championing the memory of the great men gone from us, we do not think that the neglect of which he complains has occurred widely or is in evidence in the last Lumleian lectures

MIGRATION OF SHELL FRAGMENT FROM THE FEMORAL VEIN TO THE RIGHT VENTRICLE

IN the *Journal of the American Medical Association* of Feb 7th Professor H M Lyle, of Columbia University, has reported a remarkable case observed by him when in France acting as chief surgeon of the Ambulance d'Annel, Oise A Zouave, aged 31, was brought to the ambulance Fours hours previously he had received a perforating shell wound of the left thigh, 4 cm above the knee, and a penetrating shell wound of the right thigh Radioscopy of the thigh and lower abdomen failed to reveal any foreign body Unfortunately the upper abdomen and thorax were not examined The failure to find the shell fragment was puzzling, as the depth and direction of the wound seemed to preclude the possibility of the particle having fallen out The patient was in a condition of mild shock The temperature was 97 2°F, the pulse 126, and the respiration 28 Physical examination of the chest and abdomen was negative Contused skin was cut away, the wound was laid open, and the projectile track lightly but methodically excised No foreign bodies were discovered. At the bottom of the wound of the right thigh the femoral vessels were found embedded in a clot, the femoral vein was bruised, but apparently intact Two Carrel instillation tubes were inserted and 20 c c of Dakin's hypochlorite solution were delivered to the wound every two hours The patient appeared drowsy and slept the greater part of the first two days On the third day the abdomen became greatly distended, and he complained of pain and tenderness over the spleen and right kidney The distension was partially relieved by lavage and enemas Jaundice appeared on the morning of the fourth day, and was accompanied by pain and tenderness over the liver The temperature rose to 102 2°, the pulse to 132, and the respirations to 32 Fine moist râles were heard at the left base The area of cardiac dullness increased, a pericardial rub was heard, and the cardiac sounds were indistinct A provisional diagnosis of general gas bacillus infection with pericarditis and pneumonia was made In the afternoon there was a temporary improvement, followed by sudden death a little later Throughout the wound remained sterile At the necropsy the wound of the right thigh was found to be 10 cm below and 5 cm. posterior to the anterior superior spine of the ilium The track led forward, downward, and inward to the femoral vein In the external wall of the vein there was a small valve like wound sealed by an organised clot There was no local evidence of gas infection Both the lungs were œdematous, there was fibro purulent pericarditis with free gas in the pericardial cavity The heart was enlarged, and its external surface was covered with a fibro purulent exudate On section the heart showed gaseous crepitation A rough shell fragment was found free in the cavity of the right ventricle, measuring 1 5 cm by 0 9 cm by 0 5 cm, and weighing 1 81 gm. Fibres of clothing were adherent to the irregular surface of the fragment. The liver, spleen, and kidneys were enlarged On section all yielded gaseous crepitation There was no obstruction to the gall bladder or gall ducts Evidently the fragment of shell entered the femoral vein and thence migrated to the heart A radioscopic examination of the chest might have revealed the presence of the shell fragment, which could have been dealt with by operation Bullets in the cavity of the heart have already been extracted with success in the present war

THE CLEARING OF THE PAVEMENT

THE sanitary state of our streets is important, and considerable inconvenience is sometimes caused by the present shortage in the regular service for ensuring it It ought not to be too much to ask householders, shopkeepers, and others to keep the pavement in front of their holdings swept. The work for each individual would entail neither much time nor energy If such individual civic responsibility had been insisted upon last Monday in the metropolis after the heavy fall of snow the appalling state of slush on the pavements would have been prevented As it was, the pedestrian found walking to be both dangerous and uncomfortable, and we have little doubt that a crop of minor accidents occurred through a slip on the pavement Apart from these, the constant wading through the slush was a real ordeal for the feet, few boots appearing to be proof against its penetrative powers The pedestrian whom the state of the pavement has cost an illness or an accident may well ask why the obvious remedy is not enforced

ANTIMENINGITIS INOCULATION

IN the summer of 1916 a mild epidemic of cerebro spinal fever occurred in an infantry regiment of over 1200 men at Fredriksstad in Norway Eight cases occurred, and as isolation of the patients and their contacts seemed ineffective in preventing the spread of the disease Dr E Aaser was detailed in August to make a bacteriological investigation of the epidemic This he did by the microscopical examination of smears, stained by Gram's method, of the naso pharyngeal mucus of every man in the regiment Time and the necessary facilities for any more accurate method of examination were lacking, Dr Aaser says[1] that he isolated as meningococcus carriers all the men whose naso pharyngeal mucus contained a large majority of Gram negative diplococci, and regarded as "doubtful" cases those whose mucus contained a few such diplococci He found 87 carriers and 70 doubtful cases among the men of the three regimental companies in which cases of cerebro spinal fever had occurred, no such cases had occurred among the 280 men of the fourth company or among the 100 regimental cyclists, and Dr Aaser discovered 40 doubtful cases among these but no meningococcus carriers To stop the spread of the epidemic it was decided to offer to inoculate every man in the regiment with a meningococcal vaccine It so chanced that one of the meningococcus carriers, isolated by Dr Aaser, developed meningitis next day and died This fact, coupled with fear of the meningococcus carriers, induced all but two or three of the men to be inoculated The vaccine used was a sterilised emulsion of cultures of eight or ten strains of meningococcus, containing 300 million cocci per c c the dose was 1 c c The inoculations were carried through in ten hours A few of the men had slight chills and head ache during the night following the inoculation, but none were seriously incommoded, most had a redness and swelling measuring 3 × 5 cm at the site of inoculation Dr Aaser injected himself with 3 c c of the vaccine without any ill result, and a few days later took a second injection of 4 c c equally without any general reaction The plan had been to give all the men a second inoculation four or five days after the first There was some unwillingness at this point but it happened that a general order was issued just then stopping all leave for the rest of the training in the case of those not vaccinated So all the men received a second inoculation, the dose being 1 c c In general this produced more local redness but less local swelling, and a weaker general reaction than the first inoculation No further case of cerebro spinal fever occurred in the regiment after this vaccination, during the general autumn manœuvres, but whether *propter* or merely *post hoc* Dr Aaser does not attempt to decide He notes that a similar prophylactic anti meningitis vaccination was carried out in the winter at Tönsberg, 250 men receiving three successive inoculations with 1, 2, and 3 c c of meningococcal emulsion, without any harmful result

THE CONSERVATION OF MILK

THE prevention of waste would go far to solve the food problem at the present time, and one of the most promising ways of doing this is by preserving perishable foods Liquid foods are specially liable to loss and contamination, and should therefore be desiccated Methods which in the past have been found wasteful may well now prove to be economical in view of shortage and advanced prices We shall soon arrive at the period of the year when the maximum output of milk is reached, and the waste of this valuable fluid food material is notorious Its preservation by concentration with the addition of sugar is already severely handicapped by the shortage of the preservative itself, besides which the milk syrup so produced is not ideal *for general food* purposes Milk, of course, can be concentrated without the addition of sugar, but the product cannot be said to be satisfactory, as it is very liable to chemical changes, involving, for example, the precipitation of its milk sugar and of calcium salts, chiefly in the form of citrate The desiccation needs to be carried a step further and the whole of the water removed But there are two difficulties about the complete drying of milk The first is that if too high a temperature is employed the constitution of the milk is seriously disturbed the albumins are coagulated, enzymes are destroyed, the fat is separated, and the resulting powder does not re form an emulsion with anything like the appearance and character of milk Nevertheless, the product thus obtained possesses a high nutritive value and would save much waste of useful food, particularly in the summer The water can, however, be easily withdrawn from milk by another process, which consists first in concentrating the fluid at a low temperature in a vacuum pan and then forcing the concentrated milk through a spray producer into a capacious chamber through which flows a current of warmed air The moisture is thus carried away and a fine dry powder falls, which may be swept out This product amalgamates perfectly with water, the fluid tasting like fresh milk and having exactly the appearance of the natural emulsion Moreover, it still shows enzymic activity, the albumins are uncoagulated, the fat is not separated, and caseinogen is still present in unaltered form But by whatever process dried milk powders are made one great trouble arises sooner or later the fat deteriorates, becoming partially rancid, and giving the product a repulsive flavour and smell Even skim milk, retaining as it invariably does a small proportion of fat, deteriorates in the same way sufficiently to make it distasteful after a time If this problem could be solved there would be no longer any reason for employing fluid milk at all and an enormous economy of valuable food material would be gained We could then, so to speak, keep the cow in the larder to be drawn upon exactly as domestic necessity arises The resulting revolution in the supply and distribution of milk would bring substantial gain to the community on many counts

DR Frederick Taylor was re elected President of the Royal College of Physicians of London on Monday last

AT the Harveian Society of London, Stafford Rooms, Titchbourne street, Edgware road, W 2, on April 19th, at 8 30 P M, Dr P J Cammidge will read a paper on the Treatment of Diabetes by Alimentary Rest

LEICESTER ROYAL INFIRMARY —The 144th annual report states that during the year 1916 the number of adult in patients admitted to the civil wards was 2888, as compared with 3032 in the previous year, and of children 645 compared with 616 To the military wards 571 patients were admitted during the year compared with 692 in 1915 The average number of beds occupied was 190 (civil) and 85 (military) Although the expenditure for the year was heavy—namely £31,855—it had been met by a generous increase in the ordinary income, the year closing with a small credit balance The report urges the need for a new pathological department at an estimated cost of £5000 or £6000

A RECORD OF
61 CASES OF NEOPLASMATA OF THE SKIN TREATED BY X RAYS OR RADIUM[1]

BY A A RUSSELL GREEN, M B, B S LOND, M R C S,
CAPTAIN R A M C (T) RADIOGRAPHER TO THE FIRST SOUTHERN GENERAL HOSPITAL AND TO THE BIRMINGHAM AND MIDLAND SKIN HOSPITAL

THE neoplasmata of the skin here reported are all of a malignant character The writer caused to be circularised every case of this nature which had attended the Electrical Department of the Birmingham Skin Hospital during the last four years and in the results here set down there has been no selection of cases, some indeed coming for treatment with the knowledge that no permanent benefit could be expected To 61 inquiries, 41 replies were received the majority reporting in person

Table I —This group of cases, 27 in number out of the 41 whose *final history I have traced* represents the cases that have completely healed, two only *having relapsed* at a later period Nos 1 to 20 have been treated with radium Nos 21 to 23 have been treated with X rays, and Nos 24 to 27 have been treated with X rays and radium With the exception of No 17, which is Paget s disease of the nipple, and No 27, which is epithelioma, they are all cases of rodent ulcers It is a notable feature in this group that in only three instances has any *method of filtration been employed* No 16 was filtered *through 0 25 mm* of aluminium and Nos 21 and 23 through 0 75 mm of aluminium It was also noticeable that while in some cases reaction was brought about by the treatment, in others it was absent, and in No 26, which had *several marked reactions* under X rays, no improvement took place until radium was applied, and I consider reaction as an incidental rather than an essential part of the curative process

The view once held that X *rays act purely through* their destructive effect on the tissues is untenable, as anyone who has seen treatment of *ringworm* by this means will realise

One of the points upon which I desired to get evidence was as to whether in cases treated with radium small frequent doses or larger doses at longer intervals were more efficient An examination of Table I shows that where the initial exposure was over half an hour, the average duration of treatment was 5½ months, while in those in which it was half an hour or less, the average was 10 months Of the nine cases treated with small doses six refused to heal until applications varying from three-*quarters of an hour to six hours were given*, *the other three* healed under the smaller doses, two have remained healed, the third *has relapsed* These three cases healed within three months

The other case in this group (No 18) which relapsed was treated by hourly applications of radium, increased later to six hours, and healed in six months After the relapse the patient was placed under radium treatment again, and while being so treated was painted with liquor hydrarg nitrat acid (not by me), a *proceeding* which I feel prejudiced his recovery He is now attending the Radium Institute, and writes to say that his case is considered to be hopeful

Cases treated by X rays —The following three cases were treated by X rays —

No 21 had pastille doses until she reacted, five such doses in six weeks

No 22 had small doses of X rays

No 23 had half pastille doses thrice weekly, 30 applications in all, and in the latter stages of her treatment filtered through 0 75 mm of aluminium

Cases treated by radium and X rays —In all these four cases the essential curative agent has been radium

No 24 was treated with small doses of radium 12 minutes thrice weekly, healed in five months, and was given a prophylactic dose of X rays

No 25 was treated with X rays for four months without improvement She was then put on 1 hour doses of radium and after 16 applications the ulcer healed

No 26 was treated with pastille doses weekly, several marked reactions taking place, but no healing resulting The case ultimately cleared up after the application of radium in ? to 1 hour doses

No 27 was a case of epithelioma *of the hand* in a man aged 76 This case attended for two and a half years, and the lengthy *period of attendance* was *due to the difficulty* experienced in healing the simple ulcer left after the treatment, healing was finally brought about by the application *of silver nitrate*

Table II —Traced unhealed cases —Of the eight cases *treated by radium* three have ceased attendance

No 31 by *order of* the honorary surgeon under whom he first attended

No 32 was very irregular, but in any case I should write *him down a failure, as he attended for more than six months* without *any improvement*

No 35 was healed by X rays *eight years ago but relapsed* and while being treated by radium became the subject

TABLE I —TRACED HEALED CASES

TABLE II —TRACED UNHEALED CASES

Note —In the columns headed Treatment, where the sign — separates the figures the first figure indicates the number of applications, and the second figure the duration of such application

No	Age	Duration of ulcer (years)	Treatment	Duration of treatment (months)

TABLE IV

Of all cases that can be traced 66 per cent are healed, and have remained healed for the following period —

Between 3-4 years	7	Under 1 year	4
Between 2-3 years	4	Relapsed	2
Between 1-2 years	9		

Of those treated by —

Radium	70% healed.
X rays	43%
Radium and X rays	66% ,

No 17 was diagnosed as Paget s disease of the nipple No 27 as epithelioma of the wrist All other cases in this table were diagnosed as rodent ulcer of general enlargement of the lymphatic glands without characteristic blood changes, and ceased to attend

---

[1] A report to the Midland Medical Society

Of the five still attending, No 28 is making satisfactory progress No 29 is nearly healed

No 30 is of some medico-legal interest, especially to radiologists She is 58 years of age, and has had lupus as long as she can remember Thirty five years ago she was treated at the Queen's Hospital, Birmingham, by scraping and caustics, but has had no treatment since Three months ago she came to my department with an epithelioma arising within the lupus area. Had this case been treated by X rays or radium it would have been cited by the critics of these methods as being due to the treatment The prognosis is bad in cases of epithelioma arising in lupus very rapid growth resulting doubtless due to the high vascularity of the parts

No 33 is progressing satisfactorily, and No 34 is a case too deeply involved to expect any result in treatment

Of the four cases treated by X rays, No 36 is improving

No 37 is attending the General Hospital, Birmingham, and writes that he is getting much benefit from radium treatment

No 38 died from apoplexy during treatment

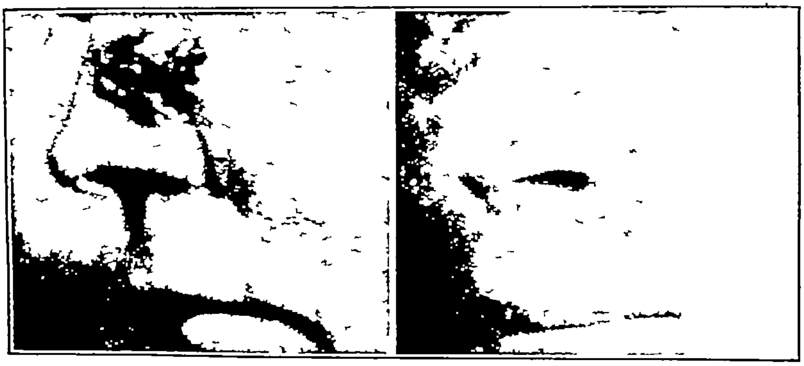
No 39 is a chronic alcoholic and ceased attendance after two and a half months

Of the two cases treated by X rays and radium, No 40 shows that improvement is possible even with such extensive involvement of the deeper tissues

No 41, a very extensive case with cicatrisation round the edges complained of such intense pain after treatment that, having regard to the bad prognosis I told him to cease to attend

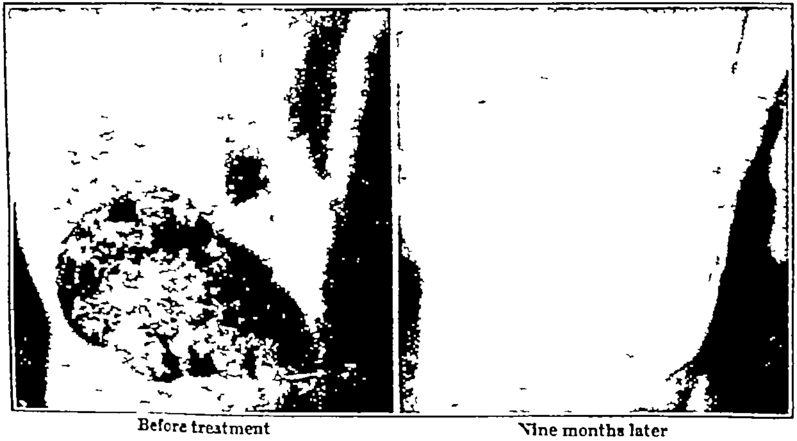
Table III — Untraced cases — I have not discarded the 20 untraced cases but by examining the out patient records (facilities for which were courteously placed in my way by the honorary surgeons) I was enabled to arrive at some conclusions concerning them 60 per cent being healed This corresponds pretty nearly with the figure obtained in the traced healed cases which is 66 per cent. Of the unhealed group four were in an advanced stage of epithelioma when they first attended the other cases on the table being rodent ulcers

FIG 1 (Case 10)*



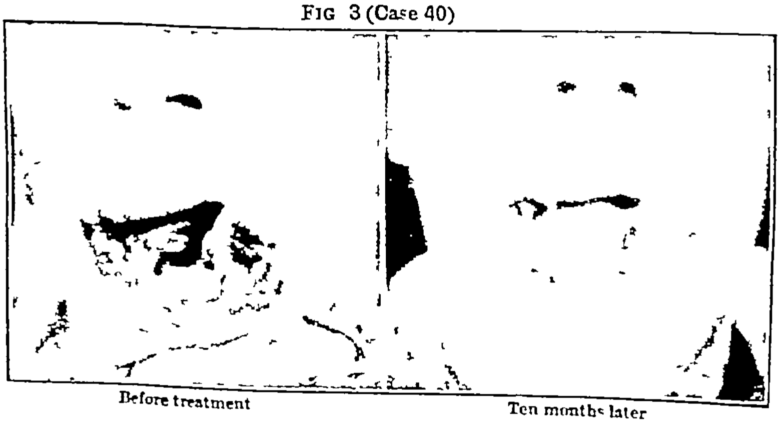
Before treatment Six months later

FIG 2 (Case 27)



Before treatment Nine months later

FIG 3 (Case 40)



Before treatment Ten months later

Method of dosage —The radium in use is pure radium bromide, and is certified as such by the Curie Laboratory It is spread on metal plates in the proportion of 5 milligrammes to each square centimetre of surface The X rays were employed as full or fractional Sabouraud doses, this being the quantity of X rays required to bring about the fall of the hair of the scalp without visible reaction, or permanent injury to the hair follicles and is a sharply defined dose

Supplementary treatment — I have found two methods of supplementary treatment useful (*a*) Electrolysis for the small nodules that are sometimes left at the periphery of the scar, and which are liable to become centres of subsequent relapse, has proved much more useful to me than the application of carbonic acid snow, in case No 27, concurrently with the first exhibition of radium, I transfixed the base of the epithelioma with an electric needle in some half dozen places (*b*) Autogenous vaccines in cases that have been obstinately septic, I have found of great value

Table IV shows the periods for which the patients have remained healed

Conclusions

To draw conclusions from so limited a number of cases is, I know, liable to mislead, but so far as these cases go they appear to demonstrate or illustrate that —

1 The administration of radium in less than one hour doses of the strength specified is likely to prove unsatisfactory, although small doses of X rays and radium will sometimes bring about healing

2. Radium will heal when X rays have failed

3 In most superficial cases screening is not necessary

4 Cases that are going to do well will do so within six months, and if they have not done so within that period a drastic revision of the treatment is imperative

5 Electrolysis and autogenous vaccines are useful as supplementary methods of treatment

6 Caustics are contra indicated

RADIUM TREATMENT IN EDINBURGH AND MANCHESTER

With a Description of

A TROCAR FOR THE INTRODUCTION OF RADIUM TUBES

ROYAL INFIRMARY, EDINBURGH

THE following abstract of the report to the managers on radium treatment at the Royal Infirmary, Edinburgh, during the year 1916 has been sent to us for publication by Dr Dawson Turner, who is in charge of the radium treatment at the infirmary

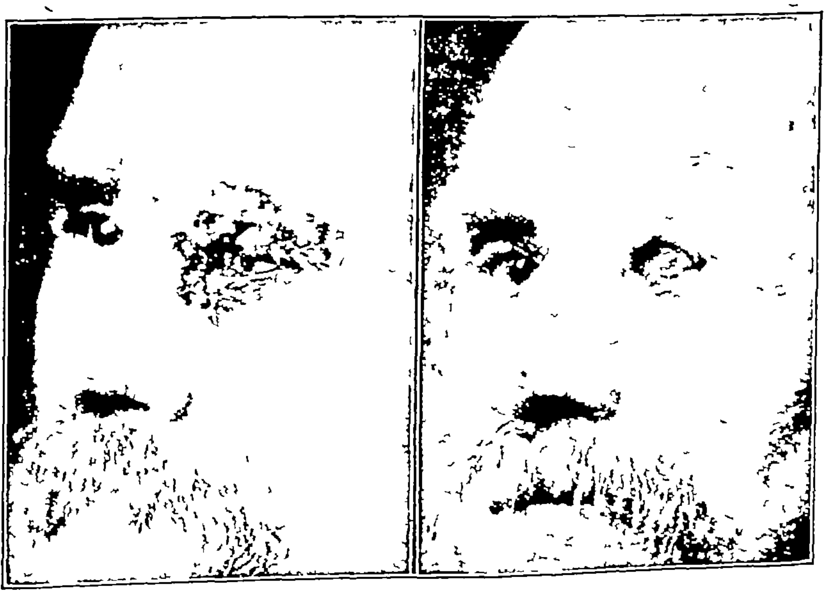
Sixty six patients attended for radium treatment during the past year, whereas 64 attended during the previous year The total attendances during the year were 520 Of the 66 patients half were in patients from other departments of the infirmary Twenty eight suffered from rodent ulcers, 25 from inoperable malignant disease, 7 of these affecting the vagina or cervix uteri There were 7 cases of exophthalmic goitre and 4 of nævi Amongst the malignant cases there were 8 sarcomas and 17 carcinomas The former are more amenable to radium than the latter, and sometimes disappear in a remarkably short time They are, in the writer's experience, invariably benefited by radium treatment, and if accessible and localised can be entirely removed Rapidity of growth is no contraindication to the use of radium, for rapidly proliferating cells are very vulnerable to its radiation, there is, in fact, reason for believing that they are more vulnerable than cells which in morphology and growth more nearly resemble the normal This has been brought to the writer's notice on certain occasions This leads to the important question, "Are all sarcomas equally amenable to radium treatment?" If a negative answer must be given to this—then what conditions determine a tumour's sensitiveness? Gaarenstroom, of the Amsterdam Cancer Institute,[1] is of the opinion that the histological structure is the chief criterion and that round-celled sarcomas generally react favourably, spindle celled less so, and polymorphous-celled least so He bases this opinion upon an experience of 23 cases treated by the Roentgen rays He made no use of radium and the effect of radium rays may not be quite the same as the effect of Roentgen rays At any rate, the writer has frequently had rodent ulcers sent to him for radium treatment which have been treated unavailingly by Roentgen rays, and these rodents radium has cured This may have been due, it must be admitted, to a more appropriate dosage and closer apposition Myelosarcomas, lymphosarcomas, large spindle celled sarcomas, and parotid mixed celled tumours are extremely sensitive, in the writer's experience, to radium rays (*Vide* Cases 1, 3, and 10)

Malignant disease of the vagina and cervix is favourably affected by radium treatment, and epitheliomas, if localised can confidently be expected to disappear Owing, however, to the difficulty of efficiently raying the more inaccessible portion of the growth, recurrence in these positions after a longer or shorter period of time is common This can be again subjected to treatment, but, as a rule, less successfully than the primary growth, and this for two reasons the one that the recurrence is probably situated in a less accessible position, as in an extension to the broad ligaments, the other that after a course of raying only those cells survive which are refractory to the rays and a recurrence consisting of such cells or daughter cells is less susceptible to attack There is a tendency by natural selection to breed cells which are immune The same phenomenon can sometimes, though rarely, be observed in rodent ulcers, an extended ulcer attacking perhaps bone or mucous membrane after repeated raying does not respond at all In these cervical cases, even though there should be recurrence, the patient has greatly benefited in the meantime by the removal of pain, the cessation of discharges, and the general gain in health and strength This gain in general health may be striking and equivalent, as some of the continental authorities have termed it to a virtual resurrection. (Cases 6, 7, and 8)

As observed in last year's report, rodent ulcers require no detailed notice, for the beneficial action of radium is generally admitted Uncomplicated cases situated on the skin and not too extensive for the amount of available radium invariably do well If they recur, which may be due to an insufficient primary treatment, they easily yield to a second course and remain cured The cosmetic result leaves nothing to be desired, and there is scarcely any subsequent contraction of the skin The case figured is a good illustration of this They are less amenable when situated on mucous membrane Though a single strong application may suffice to remove the rodent the writer prefers, when it is possible to divide the necessary dose into two or three administered at three or four days' interval It is important, in order to prevent a recurrence, that the deeper parts as well as the superficial should receive adequate treatment

Seven cases of exophthalmic goitre, five females and two males received radium treatment All benefited save one, an acute case, who died, in less than a month after the treatment, of hyperthyroidism As mentioned in last year's report, indisputable benefit is occasioned without any necessary obvious change in the organ, though generally it is diminished in size I would again draw attention to Rave's *experiments*[2] *on* cats and rabbits He administered large doses of X rays to the thyroids of these animals, and found from subsequent histological examination that no *recognisable* changes had been produced Confirmatory results have been obtained by others It appears then, that in the thyroid gland we have a structure which, so far as histological examination can carry us, is refractory to X rays Yet there is ample clinical evidence of the beneficial effects of irradiation in exophthalmic goitre

The following are brief notes of the more important cases treated except rodent ulcers, which have been purposely



A case of extensive rodent ulcer in a man 60 years of age treated with radium On the left, the condition in January, 1916 before treatment; on the right, the same case in January 1917 after treatment excluded Reference has also been made to one or two old cases whose progress it has been possible to follow

---

[2] Vide Colwell and Russ Radium and the X Rays, p 212.

CASE 1.—Myelosarcoma of temporal region involving orbital cavity in a male aged 23, recommended by Professor Gulland Admitted Oct. 17th 1916. Duration three years Began by headaches and swelling of jaw A small operation was performed to remove the swelling Later a tumour appeared on the right temporal region On July 7th 1916, Professor Caird excised a fragment which was found by the pathologist to be a myelosarcoma. Professor Caird refused to operate. On admission there was a prominent swelling over the right temporal region accompanied by shooting pain difficulty in opening the mouth and strabismus An X ray showed that the frontal bone and upper jaw were involved On Nov 1st two radium tubes were inserted in Mr Dowden s absence by Dr White into the growth and external radium treatment was also begun. A total dose of 4920 mgh was administered. In a week s time the growth had diminished in size the headache was better and the jaw freer On Nov 28th 1916 there was no squint and no pain Professor Gulland examined him and wrote: I was delighted to see the patient to-day and to find that he had improved so very greatly He looks immensely better and I see no reason why he should not start work On Jan 23rd 1917 he continued quite well

CASE 2.—Scirrhus in a female aged 59 recommended by Dr David Huskie Admitted Nov 28th, 1916 A year ago Professor Caird removed patient s left breast for scirrhus In the line of the scar there is an ulceration with hard borders. It has been burned by Dr Huskie three times This ulcer was given a dose of 205 mgh during a fortnight A week later Mr Jardine examined her and wrote Result very successful, no more need for treatment. The ulcer and hardness had disappeared. Warned patient to report herself regularly to Dr Huskie.

CASE 3 —Recurrent sarcoma (old case) in a female aged 49 recommended by Dr Maclagan Duration four years Several operations for the removal of the growth without success. Admitted by Mr Miles on July 15th 1915 Now a large nodular mass projecting in the left suborbital region and adherent to the maxilla. Pathological report, large spindle-celled sarcoma. As Mr Miles considered the tumour inoperable radium treatment was commenced. By internal and external applications a dose of 6830 mgh was given In November 1915 she was readmitted There was now an ulcerating mass closing the left eye the mass was so friable that it was difficult to keep tubes embedded but by external treatment a dose of 5180 mgh was given During these applications the growth diminished markedly On Feb 1st 1916 the tumour had greatly shrunk and was moveable it had been fixed before. Patient better and stronger and can see normally The condition had so much improved that Mr Miles removed what was left of the growth and further radium treatment was commenced A dose of 4120 mgh was given as a prophylactic against recurrence On Nov 23rd 1916, the growth had disappeared an area of dead bone was visible the skin around healthy Mr Miles could detect no sign of recurrence

CASE 4 —Sarcoma involving lower ribs on right side in a male aged 44 recommended by Mr *Dowden* Admitted May 15th 1916 Duration about 18 months On account of a swelling in the region indicated the patient attended the surgical out patient department of the Royal Infirmary in October 1915, and Mr Jardine scraped the interior of the growth The pathologist reported that the growth was a sarcoma. The growth never went quite away and on April 25th 1916 the patient was admitted *to Mr Dowden s* wards The tumour was now increasing and as Mr Dowden was of opinion that an operation would be an extremely severe one he thought that radium might be tried Over the growth there was a cyst containing blood Radium treatment was now begun Three tubes of radium were inserted into the substance of the growth and a total dose of 7560 mhg was administered On June 14th there was considerable external swelling and discharge On July 20th the external swelling was less but there was more pain The patient reported himself at regular intervals and appeared to be gaining strength for on Nov 21st, 1916 he asked permission to resume his work as a brass finisher This Mr Dowden permitted him to do On Jan 2nd 1917 he was well and hard at work but above the original growth there was a hard tumour mass, which Mr Dowden had noticed before

CASE 5 —Myeloma in a female aged 23 recommended by Mr Dowden History: Two years ago patient complained of a gumboil on the right side of the superior maxilla. Dr Gibbs *found* a growth and recommended her to consult Mr Dowden The latter scraped out the cavity and the pathologist reported the growth to be a myeloma It lay posterior to the superior maxillary bone As a prophylactic radium treatment was recommended a tube of radium was attached to a wire and passed up into the cavity and a dose of 1920 mgh administered This was in October 1915 In February 1916 there was no trace of a recurrence but when the patient reported herself in June 1916, Mr Dowden found that the disease had returned On June 27th Mr Dowden scraped out the cavity and inserted radium tubes at first three but on one coming out only two were kept in A dose of 4400 mgh was now given more than double the dose she was given the first time Precautions were also taken to attempt to maintain the radium in a more effective position Very severe reaction followed with swelling and pain which required constant opiates the tongue and mucous membrane of the cheek being burned In December the patient was much better and on Jan 2nd 1917 Mr Dowden could find no trace of a recurrence

CASE 6 —Sarcoma of cervix in a patient aged 47 recommended by Dr Barbour Admitted July 20th 1916 Duration one year Complains of a bearing-down pain and some discharge On June 26th 1916 the cervix found to be ulcerated by Dr Fordyce was curetted Pathological report sarcoma Dr Barbour examined her on July 20th 1916 and found hard nodules all round the cervix except posteriorly The right ligament was thickened Body of uterus unaffected Hysterectomy unsuitable A dose of 4500 mgh of radium was given Sept 26th 1916 Examined by Dr Fordyce Condition very satisfactory there being no trace now of the indurated nodules but cicatrisation instead Nov 14th 1916 Parts seemed quite healthy no discharge patient much stronger Weight 8 st 13 lb Feb. 1st 1917: The patient was examined and the parts found to be *in statu quo*

CASE 7 —Squamous epithelioma growing from vaginal roof behind and to left of cervix in a patient aged 63 recommended by Dr Orr and Dr W Fordyce. Admitted Oct 16th 1916 There is a soft fungating gangrenous mass of the size of a Victoria plum occupying the above position This was removed by operation and the base of it thoroughly scraped and pure carbolic acid applied Pathologist report: Squamous epithelioma showing marked necrosis Ten days later the mass had grown again to half its previous size very fœtid discharge some necrosis The mass was again removed and radium applied to base and a dose of 4900 mgh administered Jan 11th 1917 Dr Orr writes ' There is to-day nothing to be felt except a cicatrix and the least suspicion of ulceration. perhaps the size of a green pea, at one point of the cicatrix The patient feels and looks well and the result so far is very gratifying "

CASE 8 —Epithelioma of the cervix (An old case.) Patient aged 30 recommended *by Dr* Brewis Admitted July 6th 1915 Complaint of loss of health and reddish brown discharge Cervix widely involved uterus fixed. After curetting a dose of 6720 mgh of radium Sept. 30th Patient much better Pain disappeared Cervical cavity smaller granulations superficial a scraping still showed squamous epithelioma cells Uterus movable. In consequence of pathological report a dose of 1920 mgh was given Feb 3rd 1916 Patient greatly improved looks another woman July 20th 1916 Quite well Uterus shrivelled replaced by granulation tissue Pathologist s report from a scraping Nov 16 1916: Returned to ward complaining of continuous pain in right leg Examined by Dr Brewis under chloroform Cannot feel cervix or body of uterus but to the right there was a hard mass in the position of the broad ligament extending back to the sciatic notch of the bone The mass is a good size and fixed A scraping showed malignant cells A dose of 6,500 mgh of radium was administered • Dec 14th 1916 Rise of temperature Examination showed that the opening to the cavity was blocked A drainage-tube was introduced Jan 15th 1917: A slough came away Temperature still rises but less pain also less and only felt at night. Patient remains in a prostrate condition due to the disease and to the destruction produced by the radium Feb 2nd 1917: Patient remains *in statu quo*

CASE 9 —Chondro fibro-sarcoma in a boy aged 6 recommended by Dr J S Fraser Admitted May 9th 1916 The disease affected the left maxillary antrum causing protrusion of the cheek diplopia, and proptosis Dr Fraser removed as much as was possible of the growth by scraping but fearing that he had not eradicated it consulted with Mr Dowden with a view to the removal of the left superior maxilla Mr Dowden however was of opinion that the case was more suitable for radium Tubes of radium were introduced through an opening into the mouth and a dose of 1440 mgh. administered The patient was examined on Jan 3rd. 1917 by Dr Garretson in the absence of Dr Fraser and he was unable to detect any sign of the disease The boy appears to be perfectly well and is attending school

CASE 10 —Myeloma of the sternum (old case) in a male aged 23 recommended by Professor Gulland Admitted March 9th 1915 Duration two years Growth the size of a large cocoanut adherent to sternum Symptoms weakness and dyspnœa. Consultation with Mr Miles who considered the case inoperable Four radium tubes were introduced by Mr Miles into the growth and radium was also applied externally A dose of 13 200 mgh was administered Within a month of this treatment the growth had entirely disappeared Professor Gulland remarked in regard *to* this case that he had watched the tumour growing during the past 18 months that it was of very large size quite as big as two fists that he had been rather a sceptic as regards the value of radium in malignant disease but that he was now quite converted The growth was a myeloid sarcoma The patient recovered his health and strength and went back to work Six months later a small recurrence appeared over the sternum After a dose of 250 mgh it disappeared but was followed by an ulcer about 1 inch deep extending into the eroded sternum No pain was associated with the ulcer which slowly filled up The patient had a course of iodide of potassium on Mr Miles s advice. The patient was able to continue with his work. On Jan 13th 1916 Professor Gulland wrote This patient had a long course of inunction and of iodide of potassium before the radium treatment but without the slightest effect. The ulcer has impressed *me* more as a continued destruction of the tumour which must have started from the centre of the sternum " The foregoing appeared in last year's annual report The further history is as follows In February 1916 a swelling occurred in the left axilla which was removed by Mr Miles in March 1916 The pathologist s report was the following A difficult growth to classify There is a large amount of well-developed fibrous tissue. The cells have a tendency to arrange themselves in rounded follicles They are polygonal in shape and suggest endothelial cells in appearance and arrangement The condition I regard as a tumour formation belonging to the group of the lymphosarcomata but somewhat anomalous in character " Oct 26th 1916 The ulcer on the sternum is quite healed and the patient perfectly well

---

MANCHESTER AND DISTRICT RADIUM INSTITUTE

A report of the work of the Manchester and District Radium Institute (the Royal Infirmary, Manchester) by Dr Arthur Burrows the radiologist to the institute, deals with the period from Jan 1st to Dec 31st 1916, which saw the completion of the first thousand cases presenting themselves with a view to radium treatment during the two years since the institute was started Included in the report in addition to a general table of all the cases which have been treated is a list of all the malignant cases, excepting rodent ulcers which were well at the end of 1916 This list states the time during which the patients have remained free from symptoms or signs of disease No case of carcinoma of the breast was reported as being apparently well at the end of 1915 and therefore in this particular instance, 12 months is the maximum period during which any patient previously suffering from the disease can have been free from symptoms During the year the energies of the institute have been limited to the purely clinical side of its work, but it is hoped that as soon as circumstances permit an increase in the scope of its activities will be possible The physicist Mr Lupton, reports that 777 ordinary emanation tubes, 238 emanation tubes for needles, and 316 flat emanation applicators were made during the past year in the physical laboratory, showing an increase of 251 over the year 1915

A series of cases illustrating interesting points in relationship to radium treatment is given, and two groups of these may stimulate the reader's interest to read the report itself

Carcinoma of the breast —In this instance the best results follow the implantation of an adequate number of emanation tubes in the growth and along the course of the lymphatic vessels In some cases as many as 12 tubes have been buried at one time If the tumour be very firmly fixed to the chest wall the results are not so good, and treatment by implantation must be employed with extreme caution or the breaking down of the growth may produce an intractable ulcer Often it is better not to bury at all under these circumstances, but simply to apply plates externally It is always necessary to convince oneself that the situation and size of the growth give adequate opportunities for local repair If the growth of the breast be too large, it is best to remove it locally and to apply radium at the site of removal and along the lymphatic tract Radium is also most useful in assisting surgeons to operate in border line cases or for the treatment of inoperable glands of the neck Small scattered glands of the neck may be treated by the application of plates or larger masses by the method of burying In the latter instance the results are often most gratifying Small secondary skin nodules often disappear when treated by superficial plates, but their widespread nature inclines one to think that it is likely that X ray treatment would be the best method of dealing with them in the future It is by no means always necessary to produce a severe local reaction in order to remove a malignant growth by radium It is often done without the patient's knowledge that anything is happening at all, and increase of knowledge will, no doubt, practically eliminate the occurrence of a reaction which is a source of discomfort to the patient

CASE 1 —Female aged 72. This patient had a two years history of a swelling of the right breast with the formation of a lump in the right axilla She had only slight symptoms of discomfort. Her surgeon deemed her growth to be inoperable In the upper and outer quadrant of the right breast was a hard mass the size of a hen s egg It was adherent to the skin but could be moved somewhat on the chest wall In the right axilla was a mass of six or more hard glands adherent to one another Slight movement of them in the deep tissues was possible Five radium emanation tubes (each of 20 mc strength and contained in screens of platinum 3/10 mm thick) were buried in the breast (three) and axilla (two) for 24 hours The growth diminished much and treatment was repeated two months later with four tubes Three months later some indefinite thickening remained in the right breast one gland could be felt in the right axilla and one small supraclavicular gland had appeared Treatment was continued by the external application of radium plates screened by 1 5 mm of lead for 24 hours This was repeated six weeks later and seven months after the first application of radium all signs of the growth had disappeared

The above is an example which shows how much perseverance is sometimes necessary Other cases have cleared up more quickly, and it has not been necessary to apply plates

CASE 2 —Female aged 50 In 1913 radical amputation of this patient s right breast was performed for carcinoma. Twelve months later a nodule appeared at the inner end of the scar The nodule gradually grew and eventually broke down and ulcerated When she presented herself with a view to radium treatment she had at the sternal end of the breast scar an elliptical ulcer 3 × 2 cm It was surrounded by a zone of infiltration measuring 1 cm across and its edges were thickened hard and undermined The whole ulcer was intimately united with and fixed to the chest wall In the neck above the inner end of the clavicle was a hard rounded gland the size of a hazel nut It was not firmly fixed No enlarged glands could be felt elsewhere Looking to the nature and situation of the ulcer it was decided that treatment by external plates was the only method available The patient received nine applications of plates of a strength of 2 5 mg of radium to the square centimetre, screened by 6 mm of platinum for 25 hours, both to gland and ulcer an interval of six weeks elapsing between each application At the end of that period both the gland and the ulcer had disappeared leaving no sign of the growth

The above example shows that occasionally a good result may be obtained in an apparently unpromising case by the use of plates alone

Tumours of abdominal muscle —The three cases hereunder noted are all interesting from the point of view of diagnosis and radium treatment The first case is one of true sarcoma of the left rectus, the other two are examples of fibrosis of the abdominal muscles and chronic interstitial myositis respectively The case of sarcoma yielded very slowly to radium treatment while the other two cleared up extremely rapidly

CASE 1 —Female aged 29 In September 1915 this patient came to the Manchester Royal Infirmary for treatment of a hard growth about 15 cm long and 7 cm wide in the upper part of the left rectus abdominis The surgeon made an exploratory incision and a piece of the growth was removed for microscopic examination It proved to be a myxo fibro sarcoma On one occasion three tubes of radium emanation each of a strength of 20 mc. and screened by 1 mm of silver were inserted into the growth for 24 hours A considerable reduction in the size of the tumour resulted It was then decided to continue the treatment entirely by means of heavily screened radium plates applied externally for periods of 25 hours The patient has had nine such treatments and the growth has slowly decreased in size until at present all that can be palpated is a small elongated patch of thickening The treatment has thus been continued over a period of 14 months

CASE 2.—Male aged 42 This patient was operated on by a surgeon with a view to removing the tumour of the abdominal wall occupying practically the whole of the abdominal muscle to the right of the middle line and from the level of the umbilicus downwards At the time a piece of the growth only was removed for section but no further operation was performed The section under the microscope showed extensive fibrosis of muscle which suggested syphilis but the Wassermann reaction was negative Two emanation plates each containing 28 mc of radium emanation and screened by 1 5 mm of lead were applied to the growth for 24 hours Two months later no thickening whatever remained and no recurrence of the growth has taken place although 21 months have elapsed since the treatment was applied

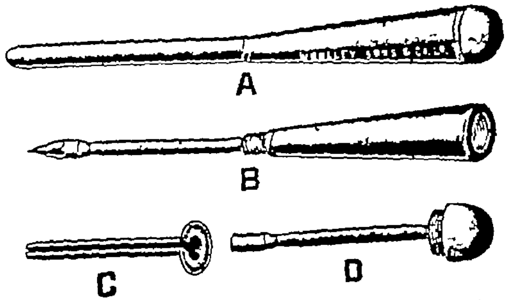
CASE 3 —Male aged 40 This patient came to the Royal Infirmary in January, 1915 He had then five weeks history of swelling of the left thigh and pain down the front of the thigh and leg A large hard fixed growth could be felt in front of the upper part of the left femur It was hard, elliptical in shape and about 15 cm long An exploratory incision was made over the tumour, and three emanation tubes containing 80 mc of emanation were buried in it A piece was removed for microscopic examination The section showed the case to be one of chronic interstitial myositis The growth rapidly became smaller and the patient has now been free of signs and symptoms for nearly two years

The classified results at the end of the year were as follows —

Free of disease at the end of the year	105	Too early to note result ..	34
Improved	317	Prophylaxis ..	20
Not improved	216	Not treated	127
Abandoned treatment	91	Total	1000
Died from their disease	90		

A TROCAR FOR THE INTRODUCTION OF RADIUM TUBES

The accompanying illustration shows an instrument which Dr Arthur Burrows has devised for introducing radium and radium emanation tubes into tumours when there is no danger of perforating important structures It consists of a sharp trocar (B), a cannula with a slot running its whole length (C) and a blunt trocar (D) The sharp trocar and the cannula are thrust into the growth to the required depth, and the trocar is withdrawn in the usual manner The radium tube is then inserted in the cannula, and its silk attachment for withdrawal is slipped into the slot Next the blunt trocar pushes the tube home The cannula is then pulled up along the trocar, and its lower end and the silk are thus completely disengaged, and the trocar and cannula are withdrawn leaving the tube in position The process is quick and practically no scar remains. The component parts of the introducer screw together into a compact whole as in A The internal diameter of the cannula is 3 mm The instrument has been made for Dr Burrows by Messrs James Woolley, Sons, and Company, Limited, of Manchester



Colonel George Henry Barefoot, C B, C M G, A M S, has been appointed a Knight of Grace of the Order of St John of Jerusalem

MEDICINE AND THE LAW

The Supervision of Poisons

THE sentence to various terms of penal servitude of three out of the four persons who were recently charged at the Old Bailey with conspiring to murder two Cabinet Ministers brought to a fitting conclusion a story of rancorous plotting against persons in authority, of perverted ingenuity, and of fatuous recklessness such as we are accustomed to associate with the cruder novel of crime or with cinematograph exhibitions The sheer improbability of many of the events might have led to acquittal if the prosecution had relied only on the reported conversations of the accused, but the discovery in the possession of one of them of substantial amounts of deadly poisons, and the most ample evidence that these poisons had been provided by another of them, placed their individual and combined guilt outside the range of doubt. We do not propose to comment upon the details of the schemes developed by the Wheeldons in their conversations with the detectives whose astuteness, combined, it would seem, with good fortune, brought them upon the spot at precisely the right moment for effective action To do so with any point would be to suggest where the proposals for murder made by the plotters might have failed or been improved. But to one thing we call attention, and not for the first time. The poison in the possession of these persons of dangerous character was deadly if they were skilful enough to use it. The fact that in this instance it might have been employed to strike a shrewd blow at the country's safety should strengthen the hands of magistrates in all cases in which irregularity in the sale of poisons is proved. The regulations governing such sales however strictly enforced, cannot be expected to prevent altogether the obtaining of poisons by the criminal, but they can no doubt, do much to limit the amount thus accessible and to render its acquirement difficult The precautions taken to prevent the surreptitious abstraction of drugs and dangerous substances from hospitals and institutions where they are legitimately stored and handled daily, cannot be expected to prevent all pilfering by persons unfit for the trust reposed in them, but the example of Mason should call attention to the necessity for the rigorous employment of such precautions and more particularly so at a time when assistants are being employed as to whose antecedents and characters there may be no trustworthy information. The element of doubt which is sometimes found in trials where poisons form the subject of expert evidence seemed entirely absent in this case The prosecution had it all their own way, and the notice of appeal which was lodged has been dismissed

The Sale of Arsenic

By an Act of Parliament passed in 1851 (14 & 15 Vict c 13) among the restrictions laid down to regulate the sale of arsenic, it is ordered that no one shall sell it 'to any person who is unknown to the person selling' unless the sale is made in the presence of a third party who is known to both vendor and purchaser In a recent prosecution brought under this Act by the police at Slough against a druggist it appeared that no legal decision has been given as to the interpretation of the expression "unknown." The druggist, who was stated to have conducted his business blamelessly for 17 years, in this case sold a small quantity of arsenic to an Australian soldier whom he had seen going about in the district for about a fortnight and who had previously made a purchase at his shop The soldier had stated that he wanted the arsenic in order to cure a fox skin The druggist observed that it should be mixed with soap for that purpose and on account of the use to which it was to be put sold the small quantity required without mixing it with soot or indigo as ordered by the Act referred to Otherwise the sale was concluded with regularity The soldier was afterwards apprehended as an absentee from his regiment and the arsenic was found upon him When the question came to be argued whether in the circumstances the purchaser of the poison was known or unknown to the vendor it was stated that a stipendiary magistrate at Manchester had held in 1857, in a similar case that the onus of proof lay upon the defendant, while on the other hand at Salford in 1859 the bench had decided that it was for the prosecution to prove that the purchaser was unknown to the druggist The Slough magistrates appear to have taken the view that the sale in the circumstances described constituted a sale to a person unknown to the druggist, for they inflicted a fine of £1 upon that charge and £2 upon a further charge of selling arsenic in less quantity than 10 pounds

A Case for Diagnosis

In a case recently tried at the Brighton county court the question arose whether the plaintiff suffered in the autumn of last year from ptomaine poisoning as the result of eating a pork pie or whether his illness was an attack of gastro intestinal influenza following a visit to a picture house The plaintiff, who had been staying at a home of rest in the neighbourhood, visited a picture house in Brighton and on returning to the station purchased at defendant's shop a pork-pie which he "washed down with a dry ginger" A friend also bought a pie, but according to the evidence only ate the crust, throwing the meat away The friend was not taken ill, but the plaintiff's indisposition necessitated a prolonged stay at the home of rest Two doctors were called to give evidence on each side Judge Mackarness commenting on the medical evidence, said that one thing the four doctors were all agreed upon was that in the absence of an analysis of the excreta it was not possible to speak with absolute certainty as to ptomaine poisoning Unfortunately no such analysis was made. It seemed he said quite possible from the medical evidence that the plaintiff might have developed influenza during his visit to Brighton, but in his opinion the medical evidence pointed to ptomaine poisoning as a very probable cause of the plaintiff's illness. He commented on the fact that there were no other sufferers among the many purchasers from the same shop on the same day, and said that it would not be right that plaintiff's misfortune should be visited on the head of defendant unless the evidence clearly established that the pork-pie was unfit for human food and was the cause of his illness The evidence fell short of that and he gave judgment for the defendant

THE CONTROL OF VENEREAL DISEASES

Approved Council Schemes

REPLYING to a question in the House of Commons on March 12th Mr Hayes Fisher, Parliamentary Secretary to the Local Government Board, stated that 20 local authorities in England had provided facilities for the free treatment of venereal diseases in 28 hospitals. The number of councils whose schemes have been approved by the Board is now 60, the list being as follows —

County Councils —Buckinghamshire Cambridgeshire Derbyshire Durham, Isle of Ely Essex Gloucestershire Herefordshire Hertfordshire Kent Leicestershire County of London Middlesex, Norfolk, Northamptonshire Northumberland Nottinghamshire, Pembrokeshire Peterborough (Soke of) Radnorshire Rutland Salop, Suffolk East Surrey Sussex East, Sussex West Warwickshire, Westmorland Wiltshire Worcestershire, Yorkshire (East Riding)

Town Councils —Bath Birmingham, Blackpool, Bootle Bradford, Brighton Cardiff Croydon, Dewsbury East Ham, Hastings Ipswich, Kingston-on Hull, Leeds Leicester London (City of) Merthyr Tydfil Middlesbrough Newcastle-upon Tyne Northampton Nottingham Portsmouth, Salford, South Shields, Tynemouth Wallasey Warrington, West Ham York.

In the case of Rutland County Council and Blackpool town council full schemes have been submitted but they are at present approved for laboratory facilities only Merthyr Tydfil Middlesbrough and York town councils have only submitted partial schemes for laboratory facilities and supply of salvarsan substitutes, and these have been approved. There remain at present 85 local authorities who have not yet presented schemes, or whose schemes have not yet been approved by the Local Government Board

The Participation of Hospitals

A White Paper issued by H M Stationery Office [OD 8509, price 1*d*] states that between 130 and 140 hospitals in England and Wales have expressed their willingness to participate in the schemes of local authorities, and although in a few instances the authorities of important hospitals have been reluctant to inaugurate during the war any fresh arrangements for the treatment of venereal diseases, this hesitation has already been overcome in some cases The shortage of medical staff and the pressure on the accommodation at most hospitals at the present time have presented obstacles in many instances but the former difficulty has been met to some extent by the Army Council arranging that certain officers of the R A M C, who are specially skilled in the treatment of venereal diseases, should devote part of their time to the work of the clinics provided at general hospitals for the treatment of these diseases

Treatment at Lambeth Infirmary

Mr A L Baly in a report upon the treatment of venereal disease at Lambeth Infirmary, mentions that all the assistant medical officers are trained to administer galyl intravenously and grey oil intramuscularly and during the nine months ended Dec 31st last 395 injections of the former have been given without a single untoward effect In some cases it has been found desirable to give more than three injections of galyl, and the number of patients presenting themselves for mercurial treatment has risen very considerably When desirable, patients are advised to remain in the infirmary until all infective lesions have disappeared, on the other hand, an increasing number of patients are admitted for week ends to receive their injections Very few men suffering from acute gonorrhœa apply for admission When admitted they receive the most modern treatment, but the ward in which they are at present accommodated is of a temporary character In regard to gonorrhœa in the female, many of the cases admitted being already in a confirmed and chronic stage only prolonged and vigorous in patient treatment appears to give satisfactory results The pathological work of the infirmary has grown to such an extent as to occupy the whole time of one of the assistants, who is an expert pathologist Mr Baly suggests that examination for specific organisms should be made in the infirmary laboratory, as well as the Wassermann reactions for examinations made for diagnostic purposes in connexion with tabes, cerebral syphilis aneurysm, and other late manifestations, and a grant claimed in respect of infective cases For the purpose of claiming Government grants, he says —

> It may be necessary to compile records showing the number of days during which patients are maintained in the infirmary suffering from venereal disease during the infective stage apart from their maintenance for any other cause or for a continuation of their treatment after the infective stage has passed I propose this should be done by keeping a special index card which will show (1) date of admission (2) the date on which in the medical officer s opinion the patient ceased to be infective; (3) the number of days so maintained I suggest that the latter date (2) should be determined by the cessation of any infective discharge and the healing of all infective lesions and in the case of gonorrhœa when the gonococcus can no longer be found by microscopic examination I propose that the guardians should claim a grant under the following conditions (i) Primary syphilis (ii) all recognised secondary syphilitic conditions (iii) rupia (iv) congenital syphilis when associated with infective lesions (v) all forms of gonorrhœa, excluding ophthalmia neonatorum in which an infective discharge is present as demonstrated by the presence of the gonococcus

The Cooperation of the General Practitioner

In connexion with the public provision for diagnosis and treatment of venereal diseases, the Local Medical Committee for the County of London calls attention to the new clause which has this year been added to the panel practitioner s agreement —

> Where the condition of the patient is such as to require services beyond the competence of an ordinary practitioner the practitioner shall advise the patient as to the steps which should be taken in order to obtain such treatment as his condition requires and shall where provision is made for such services in or for the area by any public authority after consultation with the Local Medical Committee and due notice of such provision has been given to the practitioner by the Insurance Committee take such other steps as may be reasonably necessary in order that the patient may derive full advantage from the provision of such services Provided that where, for the purpose of defining the duties of practitioners as aforesaid a scheme has been prepared by the Panel Committee in consultation with the Insurance Committee and approved by the Commissioners the provision of any such scheme shall be deemed to be part of the agreement and shall be substituted for this clause

As the public provision now made is available for every member of the community and general practitioners can assist their patients to derive full advantage from the provision by drawing their attention to the times of attendance at the various hospitals, the Local Medical Committee does not consider it necessary, at any rate for the present, for the Panel Committee to put forward any such scheme. On the other hand, the Local Medical Committee emphasises the need for individual judgment —

> At the outset every practitioner should recognise his individual responsibility to exercise his own personal judgment with regard to the nature of any form of treatment to which he advises or encourages his patient to submit. A practitioner cannot send a patient to special clinics with a definite expectation that any particular form of treatment such for example as injections of salvarsan shall be adopted It must rest with the member of the staff responsible for the case to use his own judgment as to the general value of salvarsan or any similar drug and as to its applicability in the particular case In the same way the authorities of the hospital in referring a case to a general practitioner cannot dictate the form of treatment to be applied The general practitioner must exercise his own discretion as to the form of treatment which in his hands he believes will be most beneficial to his patient.

The Local Medical Committee emphasises the fact that salvarsan is on its trial, and that those who are making the freest use of it differ amongst themselves as to the indications for its use, its mode of administration, its dosage, and its dangers, and adds that it would be greatly to the public interest if the Medical Research Committee were able to make investigations into some of the difficult questions connected with the limitations of the use of salvarsan and the trustworthiness of the Wassermann reaction and to issue a report thereon The Local Medical Committee considers that it is the duty of every practitioner to take such opportunities as may be available of learning at first hand from those with large experience the details of the modern treatment of syphilis and that no blame can possibly be attached to a practitioner who, having given careful consideration to the requirements of a patient under his care, decides not to adopt or recommend any particular form of treatment

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

To be Temporary Surgeon William F W Betenson.

The following appointments have been notified :—

Fleet Surgeons : J D Hughes to Devonport Dockyard W R. Trythall to *Téméraire* and A R Schofield to *President* additional

Staff Surgeon : G T Verry to Southampton

Temporary Surgeons : B W Dakers to *Pembroke* additional H S Brown to R M Depôt, Deal E. H Hugo to Gibraltar and W F W Betenson to *Victory* additional for Haslar Hospital

ARMY MEDICAL SERVICES

TERRITORIAL FORCE

Major H A Howes to be Deputy Assistant Director of Medical Services

ROYAL ARMY MEDICAL CORPS

Majors relinquishing the acting rank of Lieutenant-Colonel on re posting : J Fairbairn R P Lewi

Major J W West to be acting Lieutenant Colonel whilst commanding a General Hospital

To be acting Lieutenant Colonels whilst commanding a Field Ambulance : Major J Powell Capts (acting Majors) P G M Elvery G F Rudkin C L Franklin A D O Carroll G H Stevenson P S Tomlinson B Johnson E M. Middleton and Temp Capt. (acting Major) C V Bulstrode

TERRITORIAL FORCE

Major H A Howes is seconded whilst holding an appointment as Deputy Assistant Director of Medical Services

Lieuts J Fraser and H W Beedham to be Captains G Bryce to be Lieutenant

TERRITORIAL FORCE RESERVE.

Lieut. Col J T R Wilson, D S O from Royal Scots to be Lieutenant-Colonel

Capt A Findlater D S O, from London Mounted Brigade Field Ambulance to be Captain

VOLUNTEER FORCE

E J Wood 5th Battalion Kent Volunteer Regiment to be temporary Lieutenant and Medical Officer

E Ellis 8th Battalion Yorkshire West Riding Volunteer Regiment (late Second Lieutenant 1st V B West Riding Regiment), to be temporary Lieutenant and Medical Officer

G Hollies 1st Battalion Shropshire Volunteer Regiment (late Lieutenant-Colonel R A M C) to be temporary Captain and Medical Officer

T W *Dewar 2nd Battalion* Perthshire Volunteer Regiment, to be temporary Lieutenant and Medical Officer

SERVICE NEWSPAPERS AMALGAMATION

The *Army and Navy Gazette* and the *Broad Arrow* will on April 21st be incorporated under the one title. *The Army and Navy Gazette the Broad Arrow and the Naval and Military Gazette.*

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS

The March issue of this journal opens with an analysis by Colonel Sir William B Leishman and Major A B Smallman of Recent Cases of Tetanus in the British Expeditionary Force with special reference to their treatment by antitoxins Some of the tables illustrating the article are remodelled upon those adopted by Sir David Bruce in an article published in THE LANCET of Dec 2nd, 1916 p 929 and "they may be read as complementary one to the other and may in this way serve to bring into greater relief the points in which the experience of home hospitals are in contrast or in accord with those acquired in the Expeditionary Force " In the reprint of a paper on Neurasthenia and Psychasthenia, read before a Conference of Medical Officers at Malta in November last, Colonel Howard H Tooth essays to define the limits of neurasthenia and the true stigmata of the disease in order that the real neurasthenic may be justly appreciated on the one hand and that the Army may not be unduly depleted on the other The Nitrogenous Food Requirements of Some of the Commoner Pathogenic Bacteria is the subject of an article by Lieutenant-Colonel M H Gordon, and the joint inquiry by Lieutenant-Colonel C M Wenyon and Captain F W O Connor into problems affecting the spread and incidence of protozoal infections of British troops and natives in Egypt with special reference to the carrier question is continued

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Lieut D R Kharas, I M S
Capt M R Hughes, Australian A M C

Drowned

Capt G L Atkinson R A M C, was a student of King's College, London, and qualified in 1896 He held appointments at King's College Hospital and at the Victoria Hospital for Children, Chelsea, and was in practice at Hampton Hill, Middlesex, prior to joining the R A.M C

Died

Lieut Col M J Whitty, R A.M C, qualified at the Royal University of Ireland in 1885, and shortly afterwards joined the Army Medical Service, from which he retired in 1906 He was later re-employed as medical officer to the Liverpool recruiting area, and died at Liverpool on March 28th

Wounded

Lieut Col W Egan, R A M C
Capt M A Nicholson, R A M C
Capt A B Chapman, Canadian A.M C
Capt A. C Falkiner, R A M.C

DEATHS AMONG THE SONS OF MEDICAL MEN

The following sons of medical men must be added to our lists of those who have fallen during the war —

Second Lieut H F Johnson, East Kent Regiment (The Buffs), only surviving child of Dr G L Johnson, of Hampstead, London, and Johannesburg, South Africa
Lieut J S R Hodgson, Dorset Regiment, elder and only surviving son of Dr H Hodgson, of Alresford, Hants
Second Lieut V F H Hugill, Royal Fusiliers, attached Royal Flying Corps, only son of Dr G F Hugill, of Balham, Surrey

MENTIONED IN DESPATCHES

The name of the following medical officer should be added to the list of names published in THE LANCET of Feb 3rd, 1917 p 201 —

Temp Capt E P Satchell, R A M C

THE REVIEW OF MEDICAL EXCEPTIONS

The Military Service (Review of Exceptions) Bill, which passed the House of Commons on Tuesday last, will give the Army Council the right of requiring disabled and previously rejected men to present themselves for examination This will throw a prodigious amount of fresh work on medical boards, who will require every possible assistance in the carrying out of a difficult task. The use by the boards of certificates from civil practitioners has been discussed, and it has been felt in some cases that personal bias has been shown leading to the exception of a man who was really fit to serve It must be remembered, however, that in many instances it is difficult for a medical board to come to a fair conclusion without a reliable clinical history of the man in question, which can only be given by his regular medical attendant In doubtful cases it would probably be wise to give medical boards power to detain an examinee under observation in a special or military hospital for a short period Such a course might be found especially useful in conditions such as doubtful cases of pulmonary tuberculosis, slight cardiac weakness when no murmurs are present, difficulty in distinguishing between functional and organic affections, and when malingering (including doping) is suspected The advantages gained would be similar to those of the observation beds in an infectious hospital or the casualty department of a general hospital—viz., the avoidance of overlooking serious disease not recognisable as such at first sight and on the other hand of attaching undue weight to transient and unimportant symptoms This course would thus in some instances prove of great advantage to the man and in others to the Army]

OBITUARY OF THE WAR

MALDWYN LESLIE WILLIAMS, M B, B S MELB,

LIEUTENANT COLONEL, AUSTRALIAN ARMY MEDICAL CORPS

Lieutenant-Colonel M L Williams, who died of wounds in France on March 3rd at the age of 31, was one of the best known among the younger men of the medical profession in Victoria After matriculation he entered Trinity College, Melbourne, and had a distinguished career as a student, graduating with honours M.B, B S, of Melbourne University in 1908, and obtaining an appointment on the resident staff of the Melbourne Hospital in the following year He was subsequently medical superintendent to the Bendigo Hospital, relinquishing this appointment to commence private practice in Bendigo On the outbreak of war he volunteered for active service and was appointed major to an Australian field ambulance which served in Egypt and France He was later promoted lieutenant-colonel and placed in command of another field ambulance, with which he was on duty when he received the wounds from which he died

Colonel Williams made many friends during his University career He gained his football blue and represented Melbourne in Inter University matches His loss will be keenly felt by a large circle who regarded him as a man of much promise in the medical profession He leaves a widow and two children

SAMUEL W HEWETSON, M D QUEBEC,

LIEUTENANT COLONEL, CANADIAN ARMY MEDICAL CORPS

Lieutenant-Colonel S W Hewetson who died at the Royal Free Hospital London, from perforative colitis, was officer in command of the 8th Canadian Field Ambulance He was born in November, 1872, at Kincardine Ontario, entered the medical school of McGill University where he was a brilliant and popular student, and graduated in 1893 Unfortunately, soon after graduation tuberculosis showed itself, and he became a patient under the late Dr Trudeau at Saranac, remaining, as did so many of Dr Trudeau's medical patients, to be one of his enthusiastic assistants at the sanatorium Readers of his autobiography published last year will recall Trudeau's warm words of appreciation of Dr Hewetson and his services His malady led him eventually to settle in the highlands of Alberta, at Pincher Creek whence, after a few years, when his health was thoroughly re established, he moved to Calgary, becoming there a popular practitioner For many years he had been an active member of the Canadian Militia, his majority in the Army Medical Corps dating from 1910 With the beginning of the war he was appointed A.D M S of the Alberta district Attached first to the 13th Canadian Mounted Rifles in January, 1916 he organised the 8th Canadian Field Ambulance, of which he was placed in command proceeding overseas to France in the spring of the same year Lieutenant-Colonel Hewetson was married, his wife having predeceased him

HERBERT JONES, M D ONTARIO,

MAJOR CANADIAN ARMY MEDICAL CORPS

Major H Jones the news of whose death overseas has been received, was born in September, 1871, taking up his medical studies at a comparatively late period and graduating from Toronto University in 1904 He then settled in practice in Hamilton Ontario After the outbreak of war he joined the 5th Canadian Field Ambulance as captain and showed himself an excellent officer, gaining his majority in November, 1915 after several months of work at the front His death was due to pneumonia, which proved fatal after a brief illness

HUGH BARR, M D GLASG, D P H,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain H Barr who fell in action in Greece on Feb 21st at the age of 35 years was born in Paisley receiving his early education at the Grammar School there It was characteristic of him that, even as a student he had decided definitely on what was to be his life s work in medicine, and it was with the view of acquiring a sound knowledge of medicine preparatory to embarking on the study of public health that several of the years immediately following graduation were devoted by him to hospital practice in England Having obtained the diploma of Public Health, he visited Germany, where he studied bacteriology under Professor Dunbar at Hamburg, soon becoming fluent in the language Going to New Zealand about 1910 largely on account of his health, he quickly built up there a large practice, which he relinquished to accept a commission in the Royal Army Medical Corps At the end of a year s service in hospital at Salonika he returned to Scotland for a short time, being then sent to Greece His term of six months, during the latter part of which he was attached to an ambulance train, he had almost completed when he met his end

A friend who knew Captain Barr intimately speaks of him as one whose cheerfulness and ready wit could not but enliven the dullest company His mind was always active, and in its interests not confined to medicine alone His knowledge of sociology and philosophy was considerable, and extensive travelling served further to broaden his outlook His many friends can ill spare his companionship

JOHN MAXIMILIAN HAMMOND M B , B S LOND ,

LIEUTENANT ROYAL ARMY MEDICAL CORPS.

Lieutenant J M Hammond, who died on Feb 12th of wounds contracted on active service at the age of 41, was son of the late Henry A Hammond, of Bournemouth He studied medicine at Bristol University College and St Bartholomew's Hospital, London, qualifying in 1908 and holding resident appointments at the West London Hospital In 1911 he started in practice at Bournemouth, becoming medical registrar to the Hahnemann Home, relinquishing this work in the autumn of 1914 when he volunteered to go out to the English section of the French Military Hospital at St Malo Last July he was given a commission in the R A M C , sailing for Salonika in August attached to the Devonshire Regiment He was wounded by a shell during an attack on the Bulgar lines, and did not long survive an operation

A colleague writes of Lieutenant Hammond as a man who stood over 6 feet high, and of whom largeness was the prevailing characteristic "Large hearted, he was always ready to do a kindness to others Nothing was a trouble, no detail too small to receive attention At St Malo, besides treating the wounds of the *poilu*, he ministered to their souls, and with his perfect knowledge of French many was the death bed soothed by *le grand Anglais*" Fellow officers from the Macedonian front bear testimony to his good influence on the morale of the men In the end it would seem that he gave his life for them "I found I had lost my tourniquet," he says, in a letter received since his death, but the missing tourniquet was doubtless doing service to some wounded man whom he had recently tended

SYDNEY DOMVILLE ROWLAND, M A CAMB , M R C S ENG

MAJOR, ROYAL ARMY MEDICAL CORPS

Major S D Rowland, who died of cerebro-spinal fever on March 6th, was the son of the Rev W J Rowland and was born in 1872. He was educated at Berkhampsted School and Downing College, Cambridge, where he held a natural science scholarship, finishing his medical studies at St Bartholomew's Hospital in 1897 Clinical medicine did not appeal to him, and at the end of the following year he joined the staff of the Lister Institute as assistant bacteriologist, remaining attached to that institution until his death His first investigations dealt with the structure of bacteria and the enzymes in expressed cell juices, then with the late Dr Allan Macfadyen he was engaged on a long research on the juices obtained by grinding up bacteria at the temperature of liquid air In 1905 he went to India as a member of the commission for the investigation of plague, and took an important share in making out the relationship of plague bacilli to fleas and in establishing the part played by the rat flea in the dissemination of the disease On his return to England he worked on problems of plague immunity, publishing a number of valuable papers concerned chiefly with the fundamentals of prophylactic inoculation On the outbreak of war he joined the R A M C and went to France in October, 1914, in charge of the first mobile laboratory Recently he worked at meningococcus carriers, and was thus engaged when he himself succumbed to an attack of cerebro spinal fever

Major Rowland s colleagues speak of him as an exceptionally skilled mechanic whose ingenuity in getting over the technical difficulties of experimental work was of the greatest service to himself and his fellow workers His command of microscopical manipulations was also much beyond the ordinary level 'He was interested in almost everything took the cheeriest zest in life, and was never afraid of his imagination Impulsive, erratic generous to a fault, he was deeply loved by his friends '

THOMAS WILLIAM JONES, M D , D P H LIVERP ,

LIEUTENANT ROYAL ARMY MEDICAL CORPS

Lieutenant T W Jones who was killed in action on or about March 10th, at the age of 31 years, had a distinguished career as a student at Liverpool University, winning four of the five scholarships open to him—viz , the Gee Entrance Scholarship, the Junior and Senior Lyon Jones Scholarships and the University Scholarship in Medicine He was also Holt medallist and prizeman in midwifery He graduated M B , Ch B , with first-class honours, in 1908, taking his M D in the following year, and subsequently the diploma of Public Health For a year he held the Ethel Boyce Fellowship of the University After holding various resident appointments and the demonstratorship in obstetrics at the University he was appointed in December, 1912, medical officer of health for the rural district and

borough of Wrexham, and medical officer to the Wrexham education authority At the outbreak of war he was amongst the first to volunteer for service in the Royal Army Medical Corps, and although his authorities were willing to release him, it was not until November, 1916, that the Local Government Board consented to his accepting a commission. He left for France in December and in February became attached to the Northumberland Fusiliers He met his death whilst rendering assistance to a wounded man who was unable to take cover from shell-fire

As a public official Lieutenant Jones enjoyed the confidence of his colleagues The chairman of his health committee at Wrexham bears witness to his excellent work in progressive sanitation and laments the tragic termination of a career which would have benefited the public health service of the country Others speak of his duties discharged with thoroughness and efficiency, as well as with a tact which commended him to all his associates Lieutenant Jones leaves a widow and a little daughter

CECIL FRANCIS UMNEY

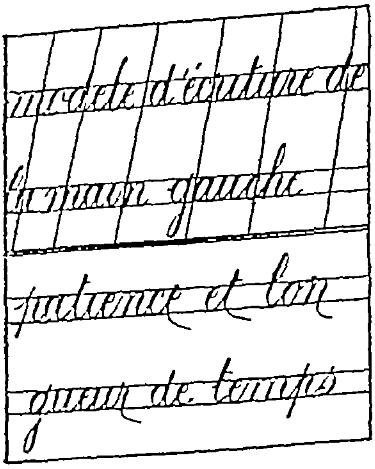
Second Lieutenant C F Umney, Dorset Regiment, who was at first reported missing but is now known to have been killed in action on Sept 26th last, was elder son of Dr W F Umney, of Sydenham. After matriculating at London University he was apprenticed to Mr W H Martindale manufacturing chemist, who writes of him as a cheerful and hard worker showing great promise in his work ' His disposition was one of the brightest, and all with whom he came in contact could not fail to like him "

EDUCATION OF THE LEFT HAND OF DISABLED SAILORS AND SOLDIERS

Dr C W Hutt writes to us in the hope that the following account may inspire further effort to assist the men in our naval and military hospitals and convalescent homes who have lost their right hand in acquiring in as short time as possible such a use of their left hand that they may in but small measure feel handicapped by their loss

At the Ecole Professionnelle de Blessés at Montpellier, since July 1915, M Tamenne, a Belgian refugee has been teaching disabled men how to use their left hands Having lost his right fore-arm when 16 years old he has so re educated his left hand that he is almost unconscious of his loss He needs no assistance to carry out the small operations of daily life he can shave himself, button collars, tie his tie and bootlaces, cut up meat, peel fruit, roll cigarettes, and get on a bicycle quite as well as a man with two hands In addition he has learnt and is able to teach writing shorthand and typewriting with the left hand only Convalescent men from the military hospitals at Montpellier needing this instruction attend at the school from 2 to 4 daily in the afternoons, some 132 have now passed through the course

FIGS 1 AND 2



The exact mode of instruction of the left hand in the operations of daily life was recently set forth in THE LANCET,[1] in an abstract of the experiences of Count Zichy, a Hungarian who losing his right arm when 14 years of age from the accidental discharge of a sporting gun, taught himself the greatest possible use of his other hand

M Tamenne, through the agency of my friend, M Edmond Dronsart Directeur Technique de l'Ecole has kindly sent me a detailed account of his method of teaching hand writing He places considerable emphasis on the men learning to write in a hand resembling as closely as possible their former handwriting This, he holds contributes in a large degree to the men losing the habit of thinking themselves as disabled or handicapped in any way To this end the writing taught has the same slope as ordinary writing, not even upright writing is allowed The position of the body is the same as when writing with the right hand, the desired slope is obtained by the position of the fingers and of the paper To write with the left hand, he says, the man should—

(1) Place his forearm comfortably on the table so as to fatigue the hand as little as possible

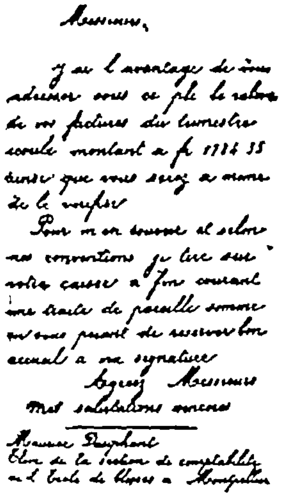
(2) Practise writing between lines about 3 5 millimetres apart

(3) Place the paper in the sloping position shown in Figs 1 and 2

(4) Try from the very beginning to give the usual slope to the letters If this proves too difficult he should draw faint lines in an oblique direction as shown in Fig 1 and endeavour to make the up- and down strokes of the letters come parallel with these lines

(5) Always take care that the hand is immediately below the point where he is writing

The man will find the last two rules difficult to carry out and the efforts to do so will tire his hand, he should leave off for a few minutes and then resume his attempts After about nine or ten lessons of an hour and a half this trouble disappears and the man is able to form the letters easily and well, the movements of the hand become more and more precise During the next 12 or so lessons he should practise writing between lines about 2 5 millimetres apart, when the letters will be the size used in ordinary writing, later, paper with single lines should be used A mistake some of the men make after five or six lessons is to try to rush their learning, with the result that they form the letters badly and lose the ground already gained Speed in writing can only be acquired with practice and time M Tamenne finds that if a man practises for more than a limited time each day he loses interest and does not do so well in the end



Copy of writing of a discharged soldier who has attended the course. His right arm is paralysed

At first the movements of the hand are uncertain but care should be taken that the letters are written as much as possible in their usual form, from the moment the man takes up his pen to the end of the last word It often happens in the formation of the last letter in a word that owing to failure of attention the pen travels below the line (See Fig 2) Patience is necessary from the start, the man must not want to get on too fast, a lesson of an hour and a half is enough for the first ten days At the end of this time the man may practise for an hour to an hour and a half in the morning and for the same time later in the day, until the time comes when he no longer experiences any fatigue during writing After two months' tuition the men are able to take their place in the commercial class ("section de comptables") and carry on as well as right-handed men This work is in a way analogous to the attempt to make children ambidextrous M Dronsart has had experience of work on these lines among elementary school children, and has found that the results obtained are not proportionate to the efforts entailed But one great factor present in disabled men is lacking in these children—necessity

At Queen Mary's Hospital for Limbless Sailors and Soldiers at Roehampton men are being taught writing with the left hand Anyone desiring to help our disabled men "se gaucher" could obtain there useful information, or better still, they should try to find a M Tamenne

---

THE NATIONAL RUMANIAN RELIEF FUND —Sir William H Dunn Lord Mayor of London and honorary treasurer of this Fund, has issued an appeal for money to provide Rumania with Red Cross equipment and to relieve distress among the civilian poor He points out that the medical services of Rumania are quite inadequate to deal with the rush of wounded now pouring in to the already crowded hospitals The address of the Fund which is under the patronage of Queen Alexandra and of Queen Marie of Rumania, is 30, Bishopsgate street, E C 2

---

[1] THE LANCET 1916 ii 231

THE PARIS CONFERENCE ON THE WAR CRIPPLE —We have received from M L de Paeuw, Secretary General of the Franco-Belgian Organising Committee, a programme of the important inter allied conference to be held in Paris on May 8th at the Ministry of Labour The conference is being called to consider occupational re education and all the questions which interest the war cripple Of the five sections, the first is devoted to physical re education, the second to occupational re education, the third to the placing of the cripple in agriculture and industry, the fourth to his economic and social interests, and the fifth to the special needs of the blind and the deaf Contributions to the discussion are solicited from all who have special knowledge, and correspondence is invited with the Secretary General at 1, rue du Bocage de Bléville, Havre

CANADIAN ACCOMMODATION FOR CONVALESCENT SOLDIERS —A Canadian correspondent writes "The Canadian Military Hospitals Commission announced on Feb 19th that there is now available in Canada accommodation for 2955 convalescent soldiers There are established a chain of 29 institutions stretching across Canada from Halifax to Vancouver Accommodation is also in sight for an additional 2200 as follows Whitby (Ontario) Hospital for the Insane, 750, Guelph (Ontario) Provincial Prison Institution, 500, Halifax (Nova Scotia) main building, Dalhousie University, 200, Winnipeg old Agricultural College, 600, Saskatoon (Sask) Y M C A, 150 The actual number of convalescent soldiers under the care of the Commission on Feb 2nd, 1917, was 1930 besides 105 in other hospitals, and 1021 out-patients There is also accommodation for 820 cases of tuberculosis in 13 sanatoria, and accommodation for 544 in preparation The actual number of patients now in sanatoria is 394 A clearing hospital for 550 men has been provided at Halifax and accommodation for 2225 more is being prepared at Montreal, Kingston, St John, Halifax, Toronto, and Winnipeg With a view to future needs accommodation has already been secured for 1589 in 19 hospitals from Quebec to Victoria, B C The total accommodation for bed cases will thus be 4364, to which 730 may be added by transferring four of the convalescent institutions to the 'active' class The total accommodation available or in sight for all classes is 10,683, inclusive of the Quebec clearing depôt, where there is room for 600"

GLASGOW AND MEDICAL MOBILISATION —At a meeting of the registered medical practitioners of Glasgow and the West of Scotland, held in the Faculty Hall on March 27th, under the auspices of the Royal Faculty of Physicians and Surgeons of Glasgow, questions arising out of the need of the Army for more doctors were discussed Dr Ebenezer Duncan President of the Faculty, was in the chair Dr McGregor Robertson's motion "that this meeting is of opinion that the time has come when the whole nation should be mobilised for the successful and rapid conclusion of the war, so that all fit persons shall be liable to be called upon by the Government to render such service in naval, military, and civil departments as they may be deemed suitable for, due regard being paid to age, training and circumstances," was unanimously adopted, as well as a further motion expressing the opinion (of the meeting) "that to compulsorily mobilise the medical profession in advance of the rest of the community would be unjust alike to the profession and the community at large" A motion proposed by Dr Charles Robertson, to the effect "that the committee to be appointed by the Government in the event of the mobilisation of the medical profession shall supersede the Scottish Medical Service Emergency Committee, and shall contain a majority of medical practitioners in active general practice," was carried by 45 votes to 42.

GENERAL HOSPITAL, BIRMINGHAM —The 137th annual report is issued with an appeal for an additional income of £7000 per annum to meet the greatly increased cost of all necessaries The number of in patients treated in 1916 was 5562, distributed as follows civilian 5230, military 332, an increase of 146 over the previous year, the daily average number in the hospital being 341, or an increase of 25 over the average of the past five years The number of children receiving treatment as in patients was 1001, of whom 214 were under two years of age The total income for the year, including special donations and grants from the War Office was £32,033 as against an expenditure of £38,811, thus leaving a deficit of £6778

THE CLOSURE OF COLOTOMY OPENINGS

To the Editor of THE LANCET

SIR —My paper on this subject in your issue of March 10th has called forth a number of letters—the best compliment that could be paid to it—which clearly show there is as yet no general agreement among surgeons as to the best method of closing colotomy openings

Mr Bernard Roth considers that his method of closing a colotomy, described in his letter of March 17th, is simpler than those I suggested, but it is difficult to see why I should have thought it was much more complicated, but apart from this, a serious objection to it is that the bowel has to be divided within the abdominal cavity, a practice which all abdominal surgeons, I think, agree in considering bad Mr Sinclair White and Mr Percival Cole both prefer Greig Smith s extraperitoneal method of closing a colotomy opening I am well acquainted with this method and have used it a number of times in the past, but I thought it was now quite dead or I should have mentioned it in my paper It appears to me to belong to the same category as lumbar colotomy and to the time when surgeons were afraid of opening the abdominal cavity What is the objection to opening the abdominal cavity? Mr Sinclair White himself says, "Every now and then the parietal peritoneum has been punctured but in no case has this made any difference" Why not then open it deliberately instead of attempting to do the operation extraperitoneally? The extraperitoneal operation is very liable to leave a weak place in the abdominal wall, and many patients have subsequently to wear belts It also leaves a condition which is not normal and is liable to cause trouble later While Greig Smith's operation may possibly be quite justifiable in old people, it is certainly unsuitable for young men wounded in the war, who have a strenuous life in front of them, and I cannot see that it has any advantage over straightforward resection and suture

My object in writing my paper was to describe (1) the easiest, and (2) the best methods of closing a colotomy There can, I think be no doubt that the enterotome method is by far the easiest, and it undoubtedly gives excellent results I have never known peritonitis follow its use, and Mr Paul, of Liverpool, who used it extensively, has not, I believe, recorded a failure with it[1] Although it is open to some of the same objections as Greig Smith's operation, it has the advantage that it involves no narrowing at the line of union and no extraperitoneal bowel There can surely be no doubt that the best method is that which restores the colon to its normal condition—namely, resection and direct suture I am surprised to hear that temporary colotomy is a common operation in civilian practice and is performed as a routine in cases of cancer of the colon unaccompanied by obstruction Why are surgeons so shy of primary resection and suture of the colon that they subject their patients to three operations where one would do? In cases of cancer of the colon accompanied by obstruction there can be no doubt as to the necessity of a temporary colotomy, but this seems an altogether unnecessary procedure in cases unaccompanied by obstruction unless other factors are present which contra indicate immediate resection and suture

After having used all the older methods, I now always perform immediate resection with end to-end suture in suitable cases and have not had a single failure to date I see Mr Finch has doubts as to the safety of getting the patient's bowels open on the second day Let me assure him that one of the secrets of success with anastomosis of the colon is not keeping the patient constipated. Flatus in the bowel is far more dangerous than a little liquid fæces The one thing to avoid is the presence in the neighbourhood of the anastomosis of masses of hard fæces and the consequent necessity for drastic purgatives If the bowels are kept acting daily by small enemata or small doses of salts the risk of leakage is greatly reduced and the colon is kept clean from accumulated and infected blood clot

I am, Sir, yours faithfully,

P LOCKHART MUMMERY, F R C S

THE LUMLEIAN LECTURES ON HEART DISEASE

To the Editor of THE LANCET

SIR,—When a few years ago Sir James Mackenzie, in a public lecture, accused physicians in general, and my teachers in particular, of preaching nonsense I passed the matter by as possibly explicable by his ignorance of what was taught in English schools, but now Dr G A Sutherland repeats the same inaccuracies, I feel bound to protest in the name of fair play and truth, and with your permission would criticise a few of Dr Sutherland's mistakes

The function of the heart, as taught to me by Sutton and Clark, was not one only—viz, that of contractility—and they were as well aware as Dr Sutherland that it had four chambers which under pathological conditions did not work harmoniously They knew a good deal about its rhythm, excitability, and tonicity as bearing on clinical medicine I would suggest that their cardiac tonics did reach the heart and so let us hope Dr Sutherland's do, or his treatment must be very feeble Valvulitis Dr Sutherland mixes up in a most casual way with the *effects* of an old endocarditis but whatever he may mean by it Sutton and Clark never taught that prognosis and treatment were based on the valvular lesion present If Dr Sutherland ever evolved from his own inner consciousness the idea that valvulitis is the central factor in heart disease it has naturally misled him, though he may still find infective endocarditis a condition that will demand a good deal of attention

Where did Sir James Mackenzie (supposing Dr Sutherland to have got it from him) get the idea that it was taught that back pressure was the *cause* of heart failure? I am sure we were never taught any such foolishness, we were taught, and I still believe it to be true that failure of the heart causes venous congestion and this in turn interferes with the function of many organs—stomach, liver, kidneys, &c The disappearance of the *presystolic murmur of* mitral stenosis was well known and was ascribed to failure of the left auricle and I still believe this is true

Perhaps after the delivery of his lectures Dr Sutherland may have time to read the late Sir A Clark's paper on Cases of Bruits without Heart Disease and Dr Sutton's Lectures on Pathology, they might save him a good deal of trouble and enable him to give more time to what is true and new instead of disseminating an inaccurate representation of what is old.—I am Sir, yours faithfully,

Harley-street, W March 21st, 1917 FRED J SMITH

PS—Of irregularity and its effects or lack of effects clinically Clark and Sutton knew as much as we do now, and tried to teach us

---

MACROSCOPIC *VERSUS* MICROSCOPIC AGGLUTINATION TECHNIQUE

To the Editor of THE LANCET

SIR—In a note in THE LANCET of Feb 17th on the effect of pyrexia on inoculation agglutinins Lieutenant G Selby Wilson, in carrying out a series of tests by the microscopic and macroscopic methods, finds that the latter gives very much higher readings than the former—that the macroscopic method is, in fact, about 30 times as sensitive as the microscopic

This marked disparity is, in my opinion, due to the different conditions under which the two series of tests were conducted and to the very different standard which he takes as the "end point" by the two methods The microscopic tests were conducted at room temperature, and the time-limit was half an hour

In his description of the macroscopic technique he does not give particulars as to temperature and time limit, but as the technique was stated to be Dreyer's, we may assume that the tubes were kept in a water bath at 55° C for two hours Thus, in three respects the macroscopic tests were at an enormous advantage over the microscopic tests—viz (1) longer time limit, (2) higher temperature, and (3) more intimate admixture of serum and emulsion by the convection currents set up in the agglutination tubes when these are placed in the water bath at 55° C All these factors especially the third facilitate the union of agglutinin with agglutinable substance and in that way make the method more "sensitive" Another factor in producing the marked disparity between the microscopic and macroscopic techniques in Lieutenant Wilson's results is that his end point by the former method is practically *complete agglutination* while his end point by the latter method *is a trace of agglutination*

If Lieutenant Wilson will conduct a series of comparative tests in which the conditions are more nearly comparable, he will find the results by the two methods more nearly coincide By removing part of the contents of the last tube which shows macroscopic agglutination for examination under the microscope, he will find agglutination microscopically—otherwise the macroscopic appearance of agglutination in that dilution amounts to an optical delusion And occasionally the first *negative* dilution macroscopically will, under the microscope show a *trace of agglutination*

The advantages of the macroscopic method are so obvious, and so well known to those who have used both that it seems hardly necessary, when comparing the methods, to do so under circumstances so unfair to the microscopic method

I am, Sir, yours faithfully,

R P GARROW M D,
Captain R A M C

Egypt, March 12th 1917

EXCISION OF THE RETRO-PHARYNGEAL GLAND

To the Editor of THE LANCET

SIR—Mr Norman Patterson's communication in your issue of last week is of interest in drawing attention to the fact that retro-pharyngeal abscess is in the great majority of cases not due to spinal disease but to disease of the retro pharyngeal gland This however, is now, I think, generally recognised

I shall be surprised if his method of operation meets with the same measure of agreement In my own experience no bad results have followed the method of operating through the mouth, and now that, with the aid of the suspension apparatus this can be carried out with so much ease and comfort, the abscess being opened and the remains of the gland curetted with precision and care so as to avoid material entering the larynx, an external operation seems unnecessary I am, Sir, yours faithfully,

Glasgow, April 2nd 1917 W S SYME

NO meeting of the British Association, which has assembled regularly since 1831, will be held this year

A UNIFIED POOR LAW AUTHORITY FOR LONDON —The London County Council adopted on Tuesday last a recommendation of its Local Government Committee in favour of setting up at once in London a Central Poor Law Authority

SOCIETY FOR THE STUDY OF INEBRIETY — At the annual meeting to be held in the rooms of the Medical Society of London, 11, Chandos street Cavendish square, W, on Tuesday, April 10th, at 4 P M, Dr R Murray Leslie will open a discussion on the Instruction of the Public in the Importance of the Prevention and Arrest of Alcoholism

ROYAL COLLEGE OF SURGEONS OF ENGLAND — Demonstrations of specimens in the Museum will be given in the Theatre of the College, Lincoln's Inn fields, by Mr S G Shattock, the pathological curator, at 5 P M each Monday, as follows —April 16th, Syphilis, 23rd, Gunshot Injuries, 30th, Gunshot Injuries The demonstrations are open to medical students and practitioners, as well as to first-aid and ambulance students

CHADWICK PUBLIC LECTURES —The spring course of lectures includes two by Captain C G Moor, R A M C (T), on the Profitable Keeping of Fowls and Rabbits on Hygienic Methods (April 12th and 19th 6 P M, at the Royal Sanitary Institute, 90 Buckingham Palace road, S W), a lecture by Dr F W Mott, F R S, on Mental Hygiene in Shell-shock during and after the War (April 26th, 5 15 P M, at the Royal Society of Medicine 1, Wimpole street, London, W), and three lectures on War Time Food, by Dr S J Moore medical officer of health of Huddersfield (April 20th and 27th, and May 4th, 7 30 P M, at the Municipal College, Lansdowne, Bournemouth) Admission to the lectures is free Particulars from the Secretary of the Chadwick Trust, 40 (6th), Queen Anne's Chambers, London, S W 1

PAYMENT FOR THE DOMICILIARY TREATMENT OF TUBERCULOSIS IN BELFAST —A Belfast correspondent writes Under the tuberculosis scheme payments are made to doctors for domiciliary treatment, and in Belfast, at the March meeting of the City Council, a list of payments made to local doctors for this purpose during the past year was presented in the Tuberculosis Committee's minutes for the approval of the Corporation The total amount was £4,536, divided amongst 101 doctors in amounts varying from £600 to 5s, payments being made according to the number of visits Among the recipients were several members of the Corporation, and the question now arises of the legality of such payments It is reported that the difficulty will be got over by some of the medical members resigning their seats, unless the question can be otherwise solved

THE ROYAL PORTSMOUTH HOSPITAL —At the annual meeting of the Royal Portsmouth Hospital held on March 27th the report for the past year was presented It stated that the number of civilian in patients treated was 2098, of military 598 that the daily average number of beds occupied was 160, and that the average cost per bed occupied was £71 11s 5d, as compared with £65 5s 6d in 1915 The year closed with a debt of £1369 The heightened expenditure of £12,308 was due to the great increase in the cost of provisions, drugs, and other necessaries Dr J T Leon, an assistant physician for 15 years, whose death had recently occurred, bequeathed £500 to the hospital The treatment of venereal diseases in the district had been taken in hand, at the invitation of the Portsmouth county borough council, the committee agreeing to coöperate with the council in carrying out the proposals of the Local Government Board on the understanding that no portion of the cost should fall upon the funds of the hospital

NOTES ON CURRENT TOPICS

Criminal Law Amendment Bill

THE Criminal Law Amendment Bill has been passed by a Standing Committee of the House of Commons and been ordered to be reported to the House One or two interesting matters were discussed in the later stages of the Bill On Wednesday, March 28th, Mr DICKINSON proposed to insert a new clause imposing a penalty on a person who, knowing that he was suffering from venereal disease in a communicable form, communicated it to another person otherwise than by sexual intercourse or by gross neglect The Bill already contained a clause dealing with the communication of disease by sexual intercourse Sir G CAVE, the Home Secretary, observed that the proposed new clause as it was framed would render it almost impossible for a person affected by venereal disease to continue to live The proposal, however, found considerable support amongst members of the Committee, and a division showed that 16 Members were on each side In the event of a tie the custom is for the chairman to give his casting vote on the side of leaving the matter open for further consideration Accordingly he voted against the proposed new clause, which was rejected A clause was brought forward by the Home Secretary to permit of the detention in an approved institution or home of a girl under the age of 18 who was convicted of importuning or solicitation The detention is to last until she is 19

National Insurance (Part I Amendment) Bill

Sir EDWIN CORNWALL has introduced in the House of Commons a Bill designed "to amend the enactments relating to National Health Insurance with respect to persons suffering from disablement in consequence of the present war" It was read a first time

---

HOUSE OF COMMONS

WEDNESDAY, MARCH 28TH

Hospital Accommodation at Sandhurst

Answering Mr EVELYN CECIL, who asked a question respecting increased hospital accommodation at the Royal Military College, Sandhurst, Mr MACPHERSON (Under Secretary for War) said Temporary arrangements have been made to provide extra hospital accommodation in the Commandant's quarters at the Staff College, where 20 beds have been allotted and during the recent outbreak of mumps certain of the halls of study were utilised Further hospital improvements are under consideration There have been two deaths, one from cerebro-spinal fever and the other from pneumonia

THURSDAY, MARCH 29TH

Dispensary Medical Men in Ireland

Mr DORIS asked the Chief Secretary for Ireland to state under what statute or by what authority the Local Government Board for Ireland claimed the right to object to the appointment of Dr George Maguire as medical officer of Newport (Mayo) dispensary district, on the grounds that he was of military age, and, if the Board had no such legal right would he advise the immediate sanction of the appointment, so that the sick poor of this district might have the medical attendance to which they were entitled —Mr DUKE replied Under the Poor Law Relief (Ireland) Act, 1851, the approval of the Local Government Board is required to any appointment of the medical officer of a dispensary district

Mr DORIS Can the right honourable gentleman give me the grounds why this gentleman was not sanctioned?—Mr. DUKE My impression is that he was not sanctioned because he was of an age when he was eligible to render much more important services to the State

Convalescent Homes for Nerve-strained Soldiers

Mr KING asked the Pensions Minister whether he would specify what arrangements were being made by his department as to the provision of convalescent homes, entirely unconnected with lunacy, for soldiers of the rank and file discharged from the Army owing to uncertifiable nerve strain where the men had cheerful surroundings and facilities for industrial occupation, and whether any allocation had been made from the National Relief Fund for this purpose under the administration of groups of local committees — Mr BARNES wrote in reply Cases of the kind referred to are being sent by local committees to ordinary convalescent homes which are entirely unconnected with lunacy A special institution will shortly be opened as an experiment at Golders Green in which men suffering from nerve-shock will be suitably treated and provided with occupation It is not intended to draw upon the National Relief Fund or this purpose

Military Service (Review of Exceptions) Bill

In moving the second reading of the Military Service (Review of Exceptions) Bill, Mr BONAR LAW (Chancellor of the Exchequer explained at length the provisions of the measure, which is to permit of the re-examination of men who have been discharged from the Army or rejected at a previous medical examination. He stated the military needs for more men, and said that the Bill would enable the military authorities to deal with a million men, from whom it was hoped to obtain 100,000 recruits In a long war like this standards had changed and must continually change Men who were rejected in the earlier stages of the war would now be taken During part of the Derby recruiting campaign an immense number of men came forward at one time There were, he believed, on one day as many as 300,000 In these circumstances medical examination was not as thorough as it ought to have been if there had been more time That was shown on the other side of the picture when many men were taken where it was a distinct disadvantage that they should have been They were taken on account of being passed improperly by medical boards If that was so, it might be assumed that some had been rejected who might well have been passed and it was not unfair that they should again be subjected to examination As to the re-examination of men, he said that the Army Council had had their lesson with regard to medical examination It was not in their interests either to take men who were not fit for service or to employ the very limited medical staff in constantly examining men who would never be fit for service

Mr HOGGE, in submitting an amendment dealing with the pension rights of men who would be brought into military service under the Bill, urged that if men passed the medical examination there should be no question of pre-existing weakness if they afterwards broke down.

Mr PRINGLE criticised at length medical examinations as they had been conducted

Mr ASQUITH said that it was assumed that the men who were going to be re-examined included men who hitherto had been exempted on medical grounds But some of them might be men who, having been originally passed and gone into the Army, had been discharged as unfit for service He did not wish to dogmatise, but so far as he had been able to familiarise himself with the facts, he was not at all sure that an equal number of men had not been passed into the Army who ought to have been It was a very disputable point as to where the balance lay No one wished to protect men who had been rejected on imperfect evidence It was perfectly right that they should be re-examined and perhaps subjected to a fuller examination

Mr BONAR LAW said that he would ask the War Office whether it was possible to make the medical examination so perfect as to run no risks of passing unfit men

Sir RYLAND ADKINS hoped that the services of civilian medical men with their varied experience of many kinds of disease should be utilised to a greater extent in conducting the medical examinations

Sir MAURICE LEVY asked for an assurance as to the thorough character of the medical examinations

Mr MACPHERSON (Under Secretary for War) said that some attacks had been made upon the medical men who had been examining recruits for the last few months There had been heavy recruiting rushes He was not surprised that some doctors did make mistakes but honourable Members would not find a Harley-street specialist looking back upon his medical prognoses and diagnoses who had made less than 1 per cent of mistakes He could confidently say that out of 1,500 000 cases the doctors had not made mistakes amounting to more than 1 or 2 per cent He thought that it was greatly to the credit of the doctors that they had performed the work to such great satisfaction.

The second reading was carried by 175 votes to 18

In the discussion in Committee on the Military Service (Review of Exceptions) Bill on Friday, March 30th considerable criticism arose on the provision which permitted men who had been discharged for wounds and sickness incurred at the front to be re-examined

Sir MAURICE LEVY moved an amendment to the effect that the medical re-examination should be undertaken by a board of not less than two medical men one of whom should be the man s own doctor if he so desired

Mr MACPHERSON pointed out that it would be impracticable to have a rule that the man s own doctor should be on the board who re-examined him The Government had already stated that the examinations would be made by competent medical boards including the best available civil medical ability Two out of every three medical men on the boards would be civilians A direction might however be given by the War Office to the medical boards to receive a certificate from a man s own doctor

The amendment was withdrawn

MONDAY, APRIL 2ND

Hygiene in T.N T Factories

Lord H. CAVENDISH-BENTINCK asked the Minister of Munitions whether his attention had been called to the fact that in some Government T.N T factories there were many breaches in the regulations designed to safeguard the health of the workers, was he aware that the exhaust ventilation provided was imperfect and inadequate, that the mess-room, cloak room, and washing accommodation was also inadequate, and that the distinction between the clean and dirty side of factories had been abandoned so that the garments of those engaged on poisonous and non poisonous processes mingled together, and would he say what action he proposed to take to improve the conditions —Dr ADDISON replied A set of rules for observance in T N T factories has recently been issued by the Ministry These embody the practice which has proved most successful in T.N T. factories, and it is my intention to ensure that the rules as published are complied with in all these factories

The Calling Up of Medical Students

Answering Sir W BYLES, Mr MACPHERSON (Under Secretary for War) wrote The arrangements at present in force with regard to all students, including medical students, are that students are not in ordinary circumstances called to the colours if, being under the age of 31 they are classified lower than B 1, or if they are 31 or over and are classified lower than A. Any student falling under this arrangement is unless in possession of a tribunal exemption, required to join an Officers' Training Corps In view, however, of the requirements of the R.A.M.C , medical students in any class who are within 24 months of taking their medical degree or licence are not called up if they join an Officers' Training Corps

TUESDAY, APRIL 3RD

Military Service (Review of Exceptions) Bill

In the course of the proceedings in report on this Bill, Mr PRINGLE moved an amendment to provide that in any case where a man examined under the measure and passed for military service produced a medical certificate that he was unfit for general service, or for any form of military service, he should be entitled to be re-examined by a special Medical Board

Mr FORSTER (Financial Secretary to the War Office) resisted the amendment on the ground that the mere fact that the man had been previously rejected would be enough to put Medical Boards on their guard in conducting the examinations

Many honourable Members urged the Government to accept the substance of the amendment Sir W COLLINS thought that there should be an opportunity of consulting specialists in these cases.

Sir J SIMON said that he was sure that Medical Boards had done their duty to the best of their resources, but they had a very hard task. It was well known that some very serious mistakes had been made, and it was desired that these mistakes should be minimised in the future It might be said that there might be cases where medical certificates given at short notice without previous knowledge of the case might not be very valuable But was it not possible that a qualification should be introduced into the amendment to secure that the certificate should only come from a practitioner who wrote with a personal knowledge of the man's medical history? The medical man might also be required to state what in his opinion was the reason why the man should not be called upon to serve

Mr FORSTER replied that all honourable Members were at one in trying to secure fair treatment for the men and fair treatment for the Army He did not want to make any reflections on the medical profession because taken on the whole it was a singularly honourable profession, but it was generally agreed that some medical certificates were worth a great deal more than others If it could be secured that all the medical certificates to be submitted to the Medical Boards were of the better character, then he would not hesitate to accept the amendment, but he was afraid that at present he was unable to accept the view that the presentation of a medical certificate by the man who was being examined ought to secure for him an examination by a special Medical Board. He clearly recognised the strong view expressed in the course of the debate and he would undertake to consult with the Secretary of State for War and his advisers before the Bill was passed, to see how far it was possible to meet the wishes of the House Further than that he could not go

The amendment was rejected by 128 votes to 44

The Bill afterwards received a third reading

THE death is announced of Emil von Behring, professor of hygiene in the University of Marburg

Vacancies.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN Park place Cheetham Hill road —House Surgeon Salary £150 per annum with board &c

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST Fitzroy square W and Northwood —Ophthalmic Surgeon

NETLEY BRITISH RED CROSS HOSPITAL.—Two Junior Medical Officers

NEWCASTLE UPON TYNE EDUCATION COMMITTEE.—Assistant School Medical Officer Salary £300 per annum

NEW HOSPITAL FOR WOMEN Euston road, N W —Female Assistant Physician and Assistant Surgeon

QUEEN'S HOSPITAL FOR CHILDREN Hackney road Bethnal Green E —House Physician Casualty House Surgeon and House Surgeon for six months Salary £100 per annum with board &c.

QUEEN MARY'S HOSPITAL FOR THE EAST END Stratford —House Surgeon

ROTHERHAM HOSPITAL.—Junior House Surgeon Salary £150 per annum with board &c

ROYAL HOSPITAL FOR DISEASES OF THE CHEST City road E C 1 —Assistant Medical Officer for Tuberculosis Dispensary Salary £350 per annum

SHEFFIELD ROYAL INFIRMARY —House Physician Salary £120 per annum with board &c

SHREWSBURY SHIRLETT SANATORIUM Shropshire —Temporary Assistant Resident Medical Superintendent Salary £300 per annum

SOUTH LONDON HOSPITAL FOR WOMEN 103 South Side, Clapham Common S W 4 —Female House Physician for six months Salary at rate of £100 per annum with board &c.

STOKE ON TRENT COUNTY BOROUGH —Temporary Tuberculosis Officer Salary £500 per annum

WEST BROMWICH AND DISTRICT HOSPITAL.—Assistant House Surgeon Salary £120 per annum with board &c.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY —Resident House Surgeon Salary £120 per annum with board &c

THE Chief Inspector of Factories, Home Office London, S W , gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Brynamman (Carmarthen)

Births, Marriages, and Deaths.

BIRTHS

JEFFREY —On March 23rd at Glenbank, Jedburgh the wife of John Jeffrey M.B F R C S E —a son

MCALLUM.—On March 28th at Scotswood Milford-on Sea, the wife of J H McAllum R A.M C —a son

MARRIAGES

FRASER—MELLOR.—On March 27th, at the Parish Church Ashton under Lyne Thomas Lochhead Fraser Captain R A M C to Dorothy Walton only child of the late Mr A E Mellor J P of Springfield View Ashton under Lyne

PEARSE—WILBURN —On March 30th at St. Saviour s Church Colgate Captain Robin Pearse F R C S C A.M C of Toronto to Amy Christine eldest daughter of Mr and Mrs E J Wilburn, The Croft Southwick

N B —A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

MEDICAL NOTES IN HISTORICAL MANUSCRIPTS THE STUART PAPERS

PART VI of the Stuart Papers, belonging to His Majesty the King and preserved at Windsor Castle has been issued under the auspices of the Historical Manuscripts Commission These papers were formerly the property of the titular King James III , otherwise the Old Pretender and his sons, Charles Edward and Henry the Cardinal Duke of York, and after the latter's death were, with some trouble, acquired by the representatives of the British Crown The papers now given to the world in six bulky volumes possess, it goes without saying, great historical value So far as matters of special interest from a medical point of view are concerned, however, there is nothing to be noted beyond descriptions of the illnesses and death of Mary of Modena (Queen of James II) references to the health of her son, the titular James III , and allusions to their respective medical attendants As bearing on these points we give the following excerpts from the calendar —

Court Physicians and Surgeons

James II to the Duke of Powis (Lord Chamberlain of the Household) —1695 June 25 St Germains —Warrant for swearing and admitting Sir William Waldegrave to be first physician to the king

James III to James Porter (Vice Chamberlain of the Household) —1701 Oct 24 St Germains —Warrant for swearing and admitting the following persons to the following places John Constable, first physician in ordinary to the King Calahan Garvan, physician to the Household

Warrants dated July 20 and 23 1706 —For Calahan Garvan and Laurence Wood to be physicians in ordinary to his Majesty (James III)

Queen Mary to Walter Crane Gentleman Usher of the Privy Chamber —1714 Nov 29 St Germains —Warrant for swearing and admitting Michael Bermingham into the place of one of her chirurgeons

James III to Joseph Farrelly Doctor of Medicine —1761 Aug 1 Avignon.—Warrant constituting him one of his extraordinary physicians

Michael Bermingham to James III —1718, May —A petition in French stating that he was a native of London and had been for several years a surgeon both at the Hotel Dieu and the General Hospital at Paris and that the late Queen Mother had in 1714 appointed him her sworn surgeon and praying to be appointed surgeon to his Majesty in reversion after Monsr Beaulieu without any wages or emoluments

Health of Mary of Modena

The Duke of Berwick to James III —1714 Feb 4 St Germains —The Queen has had a little shivring this afternoon and her pulse is quick but Doctor Garvan hopes that a breathing swett will carry it of so your Majesty need not be in paine about her "

The Same to the Same —1714 Feb 15 Versailles —' This is to give your Majesty an account that this morning at half an hour past eight I left the Queen in a very good way she had rested in the night her pulse was pretty well though not free from feavour which the doctor does not expect will leave her yet some dayes in short we have much more to hope than to feare and barr accidents we may reckon her almost out of danger

The Same to the Same —1714 Feb 17 8 30 A.M St Germains —Doctor Garvan gives an account of the Queen s condition she is, thank God in a mending way though it will come on sloughly The Physicians finds her pulse almost quite right. She looks much better and her voice is considerably stronger so that we have all reason to hope she will doe well

James III to Mr Dicconson —1714 Feb 24 Barr — My heart is now at ease intirely as to the Queen s health of which last night s letters brought so comfortable an account When nothing but strength is wanting that is soon gained For God s sake take care she manage herself and do nothing to disorder her and above all not endeavour to write too soon for as great a comfort as twould be to me to see her hand again I had much rather be longer without that satisfaction than that she should in the least incommode herself for it "

The Duke of Berwick to James III —1714 Feb 24 St Germains.—" The Queen thank God continues in a thriving way and I hope within eight dayes she may beginn to sitt up She sleeps and eats well

Queen Mary to Mr Dicconson —1714 July 5 Chaillot.— I have bathed this morning and am very well I shall know to-morrow by Mr Garvan the French doctors advice as to my drinking of waters and which they think best for me "

The Same to the Same.—1714 July 7 Chaillot — The French doctors are of opinion I should go to Plombières

The Duke of Berwick to James III —1715 April 24 St. Germains —' Your Majesty will have an account by the doctors of the Queen s sickness. I hope that the quinquina will carry it soon of but I beginn to fear her journey will not be or at least of a good while

The Same to the Same —1715 April 29 St. Germains.— The Queen thank God is free of her feavour and I make no doubt but with the continuation of her quinquina will not have it any more but I do not think it possible for her to be soon in a condition of travelling

The Same to the Same —1715 May 3 St Germains.— The Queen is much better but still very weak."

Queen Mary to Mr Dicconson —1715 May 26 Chaillot — I thank God I have no other ailement than the gout I had a great deal of peine last night but after I was a bed I grew better and I slept well I am pretty well to-day but not able to sett my foo to the ground"

The Same to the Same.—1715 May 27 Chaillot — Tho the peine in my foo is very mueech abated yett it is very red and very much swelled so that I dont think I can putt it to the ground nor will I trye if I can till to-morrow but I think it necessary Dr Garvan and Beaulieu should see it to-morow or Wednsday Therefor pray gett them a Bureau chair to com he her one of these two days that I may resolve with theyr advice what to do"

General George Hamilton to the Duke of Mar—1716 Feb 13 Paris — The Queen has no been very well with some touches of the gout."

L. Inese to the Duce of Mar—1717 Sunday Sept 5 — Queen Mary hath been much out of order of late by colics and a looseness that hath mightily weakened her She is now much better"

Queen Mary to Mr Dicconson—1717 Sept 19 Chaillot — I was farr from well all day yesterday but I have had a good night by the help of treacle and ladonom drops and am well enough to-day"

L. Inese to the Duke of Mar—1717 Monday Dec. 20 — Queen Mary herself has been and still is indisposed though without any danger She had a great pain in her hand before it swelled but now she is much more easy Her physician is not sorry that her ailments are turned to the gout"

(*To be continued*)

THE ROYAL SOCIETY OF MEDICINE AND THE JOURNALS OF MILITARY HOSPITALS

To the Editor of THE LANCET

SIR—A number of military hospitals, both here and at the front, are printing "Gazettes," and many of them contain matter which cannot fail to be of interest to the future historian of the medical aspects of the war, and it is, therefore, important that some complete sets of each should be preserved I presume that those responsible for their issue deposit the usual copyright copies at the British Museum and the other copyright libraries, but my object in writing is to urge that they should also send complete sets (preferably two sets) to the library of this Society the largest medical library in the Empire I would undertake that they would be carefully bound and preserved and would always be available for reference

I am, Sir, yours faithfully,
J Y W MACALISTER, Secretary

1, Wimpole-street W., March 30th 1917

UNTAPPED SOURCES OF STARCH

To the Editor of THE LANCET

SIR,—In an interesting book published in 1854 under the title of "Wanderings among the Wild Flowers How to See and How to Gather Them containing two chapters on the economical and medicinal uses of our native plants, by Spencer Thomson, M D, F R C S.E, reference is made to the *Arum maculatum* as a source of starch The tuber of the arum in its natural state," says the author, contains an acrid juice along with a considerable amount of starchy flour the latter when freed from the acridity constitutes a nutritious article of diet", and in the chapter dealing with the economic properties of British wild plants he adds "the root tubers of the arum or cuckoo-pint are collected and prepared for sale" In view of the great need for home-grown starch at the present time it would be interesting to know whether the arum could be cultivated with any prospect of adding to our supply In Elizabethan times arum starch was used to stiffen ruffles, and it might still serve the purpose of starching linen instead of wasting upon mere vanity any of our present scanty stock of starch

I am, Sir, yours faithfully,
CERES

"LA BAIONNETTE"

LONG years ago it was said that the true test of wit was whether it could be translated into a foreign language and lose no point thereby A mere pun will not bear this test The following extracted from the number of *La Baionnette* of March 1st, will, perhaps, pass the test —

La Paperasse

Quelqu'un l'a dit : pour tuer un homme il faut depenser son poids de plomb

Mon ami je puis vous assurer que pour le guerir il faut au moins trois fois son poids de papier

The sketch shows an officer with his right arm in a sling interviewing an army official seated at a table with enormous piles of papers stacked up at either hand and a few loose sheets lying around the room It is true that we have all heard that it takes a man's weight in lead to kill him but we have not all yet heard that it takes three times his weight of paper to cure him—and paper is so dear now This highly coloured and amusing paper looks with a comic but sympathetic eye on the medical and Red Cross work in the war and its responsible editors are M Gus Bofa and Jean Villemot who are careful to state that the sketches are purely imaginative and that no ill will must be suspected towards any medical or auxiliary staff The number costs 25 centimes and is published on Thursdays at 30 rue de Provence Paris

GUM AS A FOOD

THE question of how far gum is utilisable as food in the same way as starch and sugar is probably not yet finally settled It seems to have exercised the minds of pharmacists and medical men for a long time some affirming that orientals could live on gum alone and others denying or doubting it, supporting their denials by reference to experiments performed by well known observers or by themselves Pavy said that "gum is, doubtless susceptible of being utilised as an alimentary principle although nothing definite is known about what becomes of it when introduced into the alimentary canal" He adds 'I have experimented both upon rabbits and dogs with reference to this point" Magendie also fed dogs on gum, but they apparently soon died from inanition The varieties of gum, however, are many and their properties undoubtedly vary owing to the mixtures of different gums by natives and dealers In 1847 Mr John Savory, the President of the Royal Pharmaceutical Society of Great Britain, wrote as follows of gum arabic —

> Among the demulcent substances, gum Arabic is the most frequently used in the practice of medicine It is sometimes given alone to relieve tickling coughs by allowing it to dissolve slowly in the mouth A solution of this gum in the proportion of one ounce to a pint of barley water taken to the extent of a wineglassful, furnishes an excellent beverage in cases of inflammation of the kidneys and bladder and in the inflammatory stage of gonorrhœa. From its light and supposed digestible nature it is considered a wholesome and nutritious food thousands of the Moors supporting themselves entirely upon it during the time of harvest Hasselquist mentions in his Voyages that a large caravan of Abyssinians would have starved if they had not discovered a stock of gum Arabic amongst their merchandise, on which alone a thousand persons subsisted for two months About six ounces of this gum are sufficient to support a man for a day It is mixed occasionally with milk animal broths, and other victuals

Gum arabic is said to consist of 70 per cent of arabin isomeric with cane sugar, 17 per cent of water, and potash and lime Arabinose or arabin sugar, is a crystallisable sugar or glucose and is prepared by the action of sulphuric acid on arabin Fredrik Hasselquist was a Swedish naturalist, and one of the most eminent pupils of Linnæus Having heard Linnæus express a wish that some naturalist would explore Palestine, he embarked in 1749 and explored Egypt, Arabia and Palestine, and was about to return with a rich collection when he died at Smyrna in 1752 His valuable observations were published by Linnæus in Swedish and translated into English in 1766, under the title, "Voyages and Travels in the Levant, 1749–52."

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author and if possible of the article, should be written on the blocks to facilitate identification*

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

We cannot undertake to return MSS not used.

Offices 423, STRAND, LONDON, W C 2

MANAGER'S NOTICES

ALTERATION IN THE PRICE OF "THE LANCET"

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET Commencing with the new year, the price was raised to *8d* The rates of subscription remain as revised in October

The Lettsomian Lectures

ON

WAR SURGERY OF THE ABDOMEN.

Delivered before the Medical Society of London

BY CUTHBERT WALLACE, B S LOND,
F R C S ENG, C M G,
SURGEON TO ST THOMAS'S HOSPITAL CONSULTING SURGEON, BRITISH EXPEDITIONARY FORCE.

LECTURE I

Delivered on March 19th 1917

FOREWORD

MR. PRESIDENT AND GENTLEMEN,—I have entitled these lectures ' War Surgery of the Abdomen," but it may be asked if there is really such a thing as war surgery as distinct from civil surgery I am inclined to think that there is very little difference What actual difference there is lies in the anatomical nature of the injuries, such injuries perhaps being influenced in some degree by the high speed of the projectile, though this has, it seems to me, been very much over emphasised

Good surgical principles apply as much in war as in peace and should govern all our treatment if we wish for good results. War surgery is really largely concerned with overcoming what, in civil life, one would call ' adverse circumstances," and in striving to make war conditions as much like peace conditions as is possible It is in great degree a matter of when and where to operate and how best to move the wounded man to the place where he will win back to health

There has been, and I daresay there always will be some difference of opinion between the medical and military branches The surgeon wants to start treatment as soon as possible and to keep his patient quiet, the soldier is mostly concerned, and rightly, to clear the fighting area of the sick and wounded. There are some surgeons who are too surgical and some combatants who are too combatant The result of course, is a compromise A happy sign is the passing away of the old shibboleth, "You cannot do this—we are at war ' I should say in no previous war has the medical man had it so much his own way There is a sympathy and trust between the combatant and the medical branches which was not present in South Africa The old style staff officer, who cursed the ambulances at one time for being in the way—and soon after for being out of the way—is defunct.

The Medical Service in its present campaign is without exaggeration a wonderful organisation It shows signs of strong life for it continues to improve So good is it that we must continue to strive in every way to make it better and better, we must use every means to improve mobility and to save labour, and adapt ourselves to the ever-changing conditions of war

UTILITY OF FORMER EXPERIENCE

Of this I am somewhat doubtful It is in some ways as much a hindrance as a help In judging of the number of the wounded the proportion of killed to wounded, the accommodation required it seems to have been a help as such things alter but little though they are altering, but as a general guide to surgery it has been, if anything, somewhat of a handicap

In South Africa one learnt to treat many wounds with little respect One allowed wounds received under non surgical conditions to scab over and many became confirmed in their opinion that rest starvation, and morphia was the right treatment in abdominal wounds.

This war has proved that good surgical principles will assert themselves—that the dirty wound must be laid open and that a penetrating abdominal wound must be explored

The changing conditions of wars seem to show that surgical histories brought out after the war are largely a labour lost and a waste of time Every effort must be made to summarise and render accessible the experiences of the early months of a war for use in its later periods This has been done in the present campaign by both combatant and medical services The Army is full of schools where by lectures and demonstrations officers and men are taught new methods of warfare Although from the nature of things the same methods are not applicable in the Medical Services, a great deal has been done to spread knowledge

The Army Medical Department has issued pamphlets on various subjects wherein the experience gained has been put at the disposal of all the officers attached to the Army There is also the Medical Research Committee, whose arrangements for the interchange of knowledge by postcards, and reports which tell of the progress of cases as they pass from one unit to another, have been of the utmost value I should like to take this opportunity of asking those into whose hands such inquiries come to use their utmost power to supply the details asked for By such means treatment has been modified and improved with the knowledge gained

A series of well observed cases while the war is in progress is worth pages of statistics when the fight is over At the beginning of the war there was somewhat of a breach between the front and base in France and the base in England Now there is no such breach and the experience gained at the base is transmitted to the front and surgical procedure varied in accordance with the results

Sympathy between the different units through which a wounded man passes is essential There has always been a tendency to criticise the unit in front of you, but it is always well, if you feel critical about the condition of a patient whom you received from a unit nearer the firing line, to try to put yourself in the position of the medical officer from whom you received the patient It has often happened to me when treatment has seemed open to criticism, to find that all has been explained by a personal visit to the medical officer, or unit from which the case has been received The passing of a wounded man from one unit to another is unavoidable in war, but every attempt must be made to lessen the disadvantages by the interchange of knowledge and the cultivation of friendly, not captious criticism

There is another way in which knowledge has been diffused I refer to those medical societies which have been instituted in various areas These are, of course, largely concerned with local interests, but the work they have done has been extraordinarily good There is a society at one of the bases which has been of more than usual value, as in it medical officers, through whose hands the patient passes in his journey from the trenches to the base, have met and such meetings have been very useful in making clear to the medical officers the difficulties that are met with in the various evacuation hospitals I am quite sure that these meetings have tended to make men more sympathetic to those who are working under different conditions.

Again, I believe that one of the most useful functions of a consulting surgeon has been the carrying of facts or opinions not only from the front to the base, but from one unit to another

THE FASCINATION OF ABDOMINAL SURGERY

That it is a fascinating subject there can be no doubt It is still more or less an unknown region in surgery It is a comparatively new subject and has risen from nothing to its present position during the lifetime of most of those present. Even in civil practice there are many problems still to be solved, and naturally there must still be many more in surgery of the abdomen in war Its interest lies, perhaps in the need for rapid decision, rapid action, and in a supposed dexterity which is not required in other branches. It is the Mecca of all young surgeons—and, for the matter of that of many old ones There is more joy, possibly, over one abdominal wound which recovers than over twenty other more ordinary cases

It is a curious fact that interest in abdominal surgery is shared by the public as anybody may ascertain who has followed the discussion on the treatment of abdominal wounds in this war If the abdomen is an unknown ground to the profession it is still more so to the ordinary public—hence the interest of the layman

SURGICAL OPINION WHEN THE WAR STARTED

There is no doubt that for many years it has been held that the operative treatment of abdominal wounds was not to be advised under war conditions This was partly due to want of success, as in the Spanish American War, and partly to the fact that many military surgeons were opposed to extensive operating anywhere near the firing line, and as abdominal surgery, to be successful, must be done at once, it is obvious that it could not be undertaken with success where all operations had to be postponed to a late period Although the expectant treatment was the orthodox one when the South African War broke out, many civil surgeons hoped to prove that it was wrong Surgeon General W. F Stevenson even issued an appeal for the trial of operation. The result was, however, only to confirm former opinion, though this opinion was now held on two somewhat different grounds One school held that the expectant treatment was in itself the right procedure, the other that it was the best that could be done in war

Some people believed that wounded intestine healed sufficiently often to warrant abstention, others, headed by Makins, believed that small gut lesions were practically always fatal, and that the success obtained by the "wait and see" policy was due to the escape of the bowel, although the belly had been penetrated Makins's opinion that the small gut area could be traversed by the small bullet without injury has been proved in this war If one reads the literature of the South African War, both private and official, the reason for want of success is at once obvious—the cases arrived too late It was not so much a question of the success of the expectant treatment as a failure of the operative Operations were secondary or late, and two strikingly successful cases of resection of small gut (Messrs Neale and Tuke) were operated on within 6 and 12 hours respectively

The reason for the late operation was the nature of fighting in an unsettled country of great distances The wounded could not be quickly brought to a hospital equipped with the necessary appliances. To operate in the veld with what appliances were at hand was too disheartening It was impossible to get even moderately decent conditions There was little or no water, and, what there was was often too filthy for words—the water of dams In addition there was the plague of flies that settled on everything, and lastly the operated man could not be kept quiet, it was lucky if he could ride in a horse ambulance

The conditions were utterly different from what now pertain, and this is the first time since the rise of abdominal surgery that a great campaign has been fought in a settled country and, what is more important still, with a fixed fighting line.

The small number of figures dealt with in the South African campaign was also a source of error In order to form an adequate idea of the efficacy of any treatment it is necessary to strike an average over a large series of cases. Now, in this present war one of the difficulties of establishing the operative treatment were the runs of bad luck which any operator had to face Even now, with conditions as nearly ideal as possible, one may meet a series of nine consecutive fatal cases. This must have a very depressing effect on any young surgeon or one who is not convinced that the operative treatment is in the main the best of all Now, nine abdominal cases means roughly about 600 wounded men, taking a moderate estimate of the proportion of abdominal wounds to total wounds. As a matter of fact, in the South African campaign, a casualty list of 600 wounded was considered a large one It can therefore be seen that if an operator happened to encounter such a series it is not to be surprised at that he had doubts as to the correctness of his procedure

The statistics of the South African campaign are very defective Surgeon-General Stevenson in the official history of the war, was only able to collect 207 cases of abdominal wounds. Among them, it is stated that there were 26 laparotomies with 18 deaths, a mortality of 69 2 per cent, and according to Stevenson the mortality was really even worse. The total death rate of all abdominal wounds quoted, operated and unoperated, is given as 30 4 per cent

In his most recent work 1910 "Wounds in War" the mortality is shown as 51 6 for laparotomies, the total of cases remaining the same—namely, 207 In any case the figures are really too small to have any real value Figures show that in the present campaign a mortality of 50 per cent is a good result but such a mortality in civil practice would be considered an awful death rate to face And yet it means, looking on the bright side, many lives saved

There is no doubt that certain people shot through the abdomen in South Africa, and treated expectantly, recovered As a matter of fact, there were two officers well known in the R A M C who recovered after such treatment, and I have no doubt that a knowledge of their recovery greatly strengthened the opinion that expectant treatment was, on the whole, the best There is no doubt that such successful cases make a very great impression on one

The South African campaign may then be said to have left surgical opinion opposed to operation This opinion seems to have been only strengthened by succeeding wars—the French War in Morocco, the Balkan War, and the Russo Japanese War In the last war the results were so bad that the Japanese forbade operation in the ambulances, even in the fixed fighting round Port Arthur little measure of success was obtained On the Russian side, it is interesting to note that a Princess Gedroitz, in an operating wagon, met with some measure of success, and fixed the limit of successful intervention to three hours after the receipt of the wound It is stated, at all events, that she saved the life of a colonel shot in the small intestine

METHOD OF TREATMENT IN THE EARLIER PERIOD OF THE WAR.

It is not intended here to say anything about the period of the retreat Under such conditions adequate provision for operating near the front was an impossibility, and all that could be done was to get rid of the wounded to the base with the least possible discomfort to them When the line became fixed the conditions were very different and there was a possibility of operating under good conditions It was no longer a question of whether a man could be operated upon, but whether he should be operated upon Still however, the old belief in the efficacy of the expectant treatment obtained

In order to understand what was done during this period it is necessary to say a word or two about the standard system by which the wounded man was evacuated Shortly, it was as follows A wounded man was first seen by the regimental medical officer to whom he was brought in the regimental aid post situated somewhere in the trench system He was then transferred by a stretcher to an advanced dressing station, usually situated just behind the trenches, and from there by car to the field ambulance and there he was kept until the time the motor convoy arrived—usually once in the 24 hours By this he was taken to the casualty clearing station, which was the first place adequately equipped for operative treatment In the early days the clearing station was a very different hospital from what it is now But, still there was reasonable facility for the performance of any operation if it was thought advisable With the idea of avoiding the disturbance of movement, a man wounded in the abdomen was kept sometimes, though not usually in the regimental aid post, often he was kept at a field ambulance, but usually he was transferred to the casualty clearing station and there treated

The usual mode of procedure was to put the man in the Fowler position, to improve the general condition by rest and warmth, to withhold food and water for three days and to administer morphia The thirst which was a distressing symptom of this treatment was combated to a certain degree by rectal salines and mouth washes.

I should like here to pay tribute to the great care and attention which the medical officers lavished on the cases Certain officers were told off day and night to attend to these patients and everything that could be done to alleviate their suffering and to make them as comfortable as possible and to cheer them up was done. I should say that if anything could have got these men well the attention that they received would have done so. The people who conducted the treatment were firmly convinced of its efficacy

This belief was strengthened by the behaviour of the patient Many patients, at first gravely ill, went through a period of improvement which often was very striking It was in a way unfortunate, but there is no doubt that improvement did take place, and so well were many of them that they were evacuated to the base and arrived there sometimes in good condition and sometimes gravely ill The men who saw the cases leave them apparently on the way to recovery could not bring themselves to believe that such cases did badly at the base It was unfortunate no doubt, that the means of communication between the base and the front was, in those days, inadequate, and this serves to emphasise what I have already stated about the value of free interchange of reports between the front and the base

If evacuation of these cases had not been necessary and it had been possible to keep them at the clearing stations, I have no doubt that the expectant treatment would not have survived as long as it did, for medical officers would have seen such cases become worse and worse, and in the end die. As a matter of fact, during my six months' experience at the Red Cross Hospital at Netley, I only saw two cases of wounds of the abdominal viscera, one was a case of cæcostomy and the other a transverse colostomy

When I arrived in France in May 1915, I spent some time at the base before I was sent to the casualty clearing stations I had the advantage of learning what was Sir George Makins's experience in the unoperated abdominal cases and heard that many died who had been thought well enough to be sent to the base I had always believed that operative treatment provided adequate arrangements could be made, was the ideal thing What I saw at the base and front only confirmed me in my belief that the best hope for the patient lay in an operation. I had no doubt that many cases which were put down as penetrating abdominal ones had not suffered injury to any hollow viscus and many that were considered penetrating were really only wounds of the abdominal wall I certainly saw many people treated by the expectant treatment die even at the casualty clearing stations, some after the period of delusive improvement

The expectant treatment was also a very trying time for the wounded man The knowledge that nothing could be done for him by operation, and that the only thing was to wait events, had a very depressing effect, although the medical officers did everything to cheer them up The idea was getting about that the doctors were unable to help a man who was wounded in the abdomen, and that he had really little chance

It is curious, but true, I think that the wounded soldier welcomes operation He feels that something is being done for him. I have often been asked the question, 'Can't you operate?" If I have answered in the negative, with an assurance that operation is unnecessary and that he will do well I have often detected a look of disappointment on the patient's face I mention this as showing that operation has no horrors for the soldier

EXPERIENCES OF THE ALLIES

The French have gone through very much the same experience in the treatment of abdominal wounds At first the only operation officially blessed was that of the suprapubic drainage of Murphy Gradually they have, like ourselves abandoned the expectant for the operative treatment

I cannot do better than quote you a letter which Professor Tuffier has kindly written me He says —

Abdominal surgery has undergone in France the following revolution Until the month of February 1915, installations did not allow one to operate under good conditions, on wounds of the abdominal cavity, and abstention was necessary in these circumstances At this period I found in a small ambulance quite near the front and very well organised several cases of cure of wounds of the intestine by laparotomy I reported them to the Society of Surgery and a movement commenced in favour of operation for all abdominal wounds It is because the motor surgical ambulances and the medical arrangements have been better organised and because the evacuation of the wounded has been done in a relatively short time that we have been able to arrive at a certain measure of success.

With the French as with us the period of the retreat corresponded to the period of expectant treatment and when the line became fixed the treatment underwent the same change as it did in the British Army As a matter of fact after the establishment of the operative treatment some French surgeons have from time to time again championed the expectant treatment but this finds little acceptance with the majority of French surgeons

MORTALITY IN THE PRE OPERATIVE DAYS

One is surrounded by all sorts of difficulties in trying to reckon the mortality and all the figures that can be obtained must be considered only approximate. One of the chief difficulties is the determination as to whether a wound is really penetrating Those who favour the expectant treatment would naturally tend to include cases which those who are opposed to this treatment would exclude

Into nine field ambulances over a period of six months there were admitted 1098 abdominal wounds with 333 deaths—a mortality of 30 per cent In the six casualty clearing stations during the same period there were admitted 131 cases of perforating abdominal wounds with 73 deaths From these figures it appears that the total mortality in the field ambulances and clearing stations was about 70 per cent. This, of course, does not include the deaths before patients reached the unit where statistics are kept

There were also the deaths at the base in France to be added, and in the pre-operative days to which we now allude many such deaths occurred, which would, as far as can be judged, bring the mortality up to about 80 per cent.

As showing the difficulty of arriving at accurate figures, it may be stated that statistics were prepared by certain people which stated that 80 per cent of abdominal wounds recovered These statistics, as a matter of fact, were got from certain ambulances and casualty clearing stations in which the surgeons were enthusiastic supporters of the expectant treatment It is significant that in these units the proportion of abdominal wounds to total wounds was high

In talking over the possibility of improvement with Colonel Crisp English, with whom I was fortunately associated when trying the effect of operative treatment, I used to say that if one could bring about a reduction of the mortality by 10 per cent. one would be fortunate There was no question of revolutionising the mortality, because with the abdominal wounds there would be a very heavy mortality, and it was only a question of saving a certain number of lives which otherwise would have been lost by the expectant treatment.

COMMENCEMENT OF THE OPERATIVE TREATMENT

Although rest treatment was the rule, some attempts at operation had been tried Early in the war Souttar commenced early operation with the Belgian Army, and credit must be given to him for what he did Owen Richards was the first I believe to publish results of operative treatment in the British Army[1] The first case of operation was performed on Jan 28th 1915, and the first successful case, that of a resection of 2½ feet of the small intestine was performed on March 18th, 1915 36 hours after receipt of the injury which period still stands as a record as regards time elapsed since the wound. A few other English surgeons had tried what could be done by operation, but the results were undeniably bad—so bad that most people had abandoned the attempt The reason for this was, no doubt, the late arrival of the cases at a place where an operation could be performed

Holding the opinion that operation was right, I commenced operating and making post-mortem examinations and soon convinced myself that the injuries were as a rule, of such a nature that recovery must be a very rare event It was also found that hæmorrhage was a chief cause of early death and that bullets produced very extensive injuries It has always been granted that hæmorrhage was the chief cause of early death but the advocates of expectant treatment seem to have focussed their attention more on the danger of peritoneal infection and the possibility of its localisation or disappearance than on the possibility of spontaneous arrest of hæmorrhage

The discovery that bullets produced extensive gut injuries was also of great importance as much stress had been laid on the smallness of the lesions produced by the modern small bore bullet, in fact the hope of spontaneous recovery of gut lesions was based on the assumption that such projectiles were comparatively innocuous This idea was constantly put forward in the early period of the war

The re-establishment that hæmorrhage was the chief cause of early death was of great importance, as it showed that only by rapid evacuation could one hope to combat such a condition In June 1915 I talked the matter over with Surgeon General W G Macpherson and obtained his leave to get some of the field ambulances to send the abdominal wounds at once with all possible celerity to the nearest casualty clearing station The results obtained by this small experiment were encouraging and in the first week in August 1915 Surgeon General Macpherson gave the order which made the rapid evacuation of abdominal wounds the official method in the First Army This was followed by rapid improvement in the results obtained.

---

[1] Brit Med Jour August 7th 1915 p 2

SELECTION OF CASES FOR RAPID EVACUATION

The order to transfer all abdominal cases with celerity to the casualty clearing station put a great deal of responsibility on the field ambulance officers It is no light task to decide what cases can stand evacuation, in fact, it is one of the most difficult things that a medical officer is called upon to determine Many cases, of course, are better of a rest and food and warmth, but in the case of abdominal wounds it must be remembered that hæmorrhage is a chief cause of death and that the only hope for their salvation lies in the arrest of the hæmorrhage by surgical means It is, therefore, obvious that it is worth while taking risks in cases of abdominal wounds which it would not be right to take in other cases It is quite true that there is an appreciable danger of death from peritoneal affection, but, as a matter of fact, experience has shown that the need for celerity on this account is nothing compared to that necessary in the cases of hæmorrhage

COLLECTION AND EVACUATION OF WOUNDED

In forming a judgment on the results obtained by the operative treatment of abdominal injuries it is necessary to know something about the means by which such cases reach a casualty clearing station A knowledge of the difficulties is also necessary in order to form an appreciation of the really magnificent work which is being done by the regimental medical officer and his stretcher bearers and by the personnel of the field ambulances One can consider this subject under two heads (1) the collection, (2) the evacuation of the wounded man

1 By *collection* is meant the finding and bringing back to the regimental aid post the wounded when they lie out in front of our lines, and without going into particulars it can be well understood what the difficulties are when an attack has been made and our troops have advanced If it is difficult to find and collect the wounded after a successful attack it it still more difficult when the fortunes of battle sway backwards and forwards, and it is under the latter conditions that the wounded lie out for a considerable period In quiet times the collection is not difficult for the men are wounded very often in the trenches themselves

2 *The evacuation* —We will consider that a man has been wounded in the front trench The first field dressing most probably will be applied by himself or by one of his companions, possibly by the medical officer himself The patient will then walk, be carried, or be taken on some kind of stretcher to the regimental aid post. Even this is performed under considerable difficulties because the nature of the trench system involves getting round many sharp angles The regimental aid post is situated somewhere near the front line or in the commencement of a down communication trench It is generally in a dug out, or cellar, the accommodation is not grand, but one cannot help admiring the ingenuity with which these places are arranged and the care taken to make the surroundings as perfect as possible The neatness of such places is really greatly to be wondered at, fitted up as they are with extemporised shelves and tables and trestles for the stretchers Here the wounded man will be attended to if the regimental medical officer has not already been seen by him An adequate dressing will be applied and the ordinary medical measures taken for his comfort

Under the present system of evacuation an abdominally wounded man will not wait in this place He will be taken on a stretcher down the communication trench to a field ambulance post, which is a dug out where the field ambulance personnel are accommodated and where the regimental stretcher bearers hand the case over to the field ambulance From this point commences the long journey—sometimes as much as two miles—down the communication trench Everyone has seen pictures of such a thing, but to appreciate the physical strain on the bearers the journey has to be made by oneself Sometimes the journey is so arduous that one complete tour is all that a stretcher party can manage without a long spell of rest In summer time the air is often stifling Under foot are the duck boards or a rough brick pavement The provision of these renders walking more easy, but the surface is necessarily uneven, especially where one board joins another Sometimes a rung is out, and at other times the board is apt to tilt and get up and look you in the face Then there are the innumerable corners formed by the zigzag of the trench and made to stop the enfilade fire and limit the danger of an exploding shell, or to prevent the enemy looking straight down the trench

In winter, or after rain, the surface of the boards is greasy in the extreme, and sometimes they are completely under water At night-time the difficulties as may be well imagined, are greatly increased Sometimes the turns in the trenches are so sharp that the traverses of the stretcher have to be closed in order to allow its passage round the corners

Much ingenuity has been expended in devising stretchers for the easier transit of the wounded man, for getting round corners easily and relieving the work of the bearers, for the strain on the shoulders produces an intolerable ache in the neck In some cases the stretchers are carried on the bearers' shoulders, the wounded man's legs lying in troughs projecting past the bearer's head, the idea being to shorten the "wheel base" as it may be called, of the stretcher party In other cases the patient is carried almost upright on a stretcher that somewhat resembles the back board of a Swiss mountain porter Many wheeled stretchers have been tried, but the inequalities of the ground and the sharp corners to be turned are difficulties which have not yet been overcome Sometimes it is possible to put a man on the trolley line and run him down over the open ground In some cases the trenches have an overhead mono-rail on which a short form of stretcher can be suspended

At the end of the communication trench the patient comes to the advanced dressing station This, as a rule, is more spacious than the regimental aid post, but is often similar in construction Sometimes it is a ruined château—not quite the place that the word château may possibly call to your mind—a château is often a euphemistic name for a villa which would be equally at home in Clapham Nearly all the houses—even the workmen's cottages—in Northern France have cellars, and these cellars have been really a godsend to the wounded If the accommodation is not sufficient it is increased by dug outs These are made sometimes of heavy timbers covered with earth and sand bags, or at other times with sections of steel tubing commonly known as elephants, treated in the same way At another time a farm or cottage is used Here the cellars are again occupied or the ground floor rooms are made safe by building within them splinter proof shelters formed of steel sheets and sandbags, and in some places where the subsoil water is found at a very shallow level shelter to the wounded is given by building splinter proofs on the surface of the ground, heavily timbered and sand bagged Although the medical arrangements are here a little more extensive and a larger supply of splints and appliances are kept as a rule they are of a simple nature and used only to render the patient's transit as comfortable as possible

Although many wounded men rest here the man with an abdominal wound, if his condition permits is placed at once in an ambulance covered up with blankets, and warmed by hot bottles Here he is quickly taken in a motor ambulance to the tented section of the field ambulance As a rule, the patient will not be removed from the ambulance, but he will be looked at by the medical officer and, if his condition is sufficiently good, at once sent on to the casualty clearing station If the field ambulance happens to lie off the road to the nearest casualty clearing station the patient is as a rule, taken straight to the latter, time thus being saved

The field ambulance or, as it is sometimes called, the headquarters or tented section is usually situated in schools or some sort of public building, sometimes in cellars or dug outs if the neighbourhood happens to be unhealthy Usually such places are not shelled, but they are, as a rule well within the range of hostile shell fire.

The casualty clearing station is the first unit through which a man passes where adequate arrangements are made for operative treatment the tendency being for all units in front of this to be merely concerned in the transport of the wounded or in doing very urgent surgery such as the arrest of hæmorrhage In one of their functions—namely that concerned with operations and after treatment of cases that cannot bear further transport—our casualty clearing stations have become hospitals, and in them are all necessary paraphernalia for the performance of any surgical operation that may be required at this stage They are situated out of the usual zone of hostile artillery fire. They have been established in all sorts of buildings—schools, chateaux, asylums, tents and huts, the arrangements of course, are determined by the building. The tents have this advantage, that you can arrange your hospital as you like. Buildings are very comfortable in winter and are better lighted and more cheery, but very often are not so convenient, especially when the upper storeys have to be utilised. Huts possibly are the best of all, as they have the advantage of buildings and can be arranged on a considered plan. Unfortunately, they are not so mobile as tents.

In the recent fighting on the Somme the tented casualty clearing stations were the rule for the very good reason that no buildings were available. The general plan of these is as follows. There is a large reception room made by lashing tents together to form a dressing room. Here the wounded, arriving off the cars, are carried; here they are examined by the medical officers and particulars taken by the clerical staff. The lighter cases have their wounds dressed and are passed on to a series of tents called the "evacuation area," or they are at once put on to the train in which they travel to the base. The more serious cases are put into the "treatment area" and here their clothes are removed, they are cleaned up as well as possible, fed, and warmed. From here they are taken into the theatre, where their wounds are properly attended to, and from here they pass again into another tent in the treatment area where they remain until ready for transmission to the base.

Many clearing stations have a ward where men arriving in a grave condition are placed and every attempt is made by warmth, food, and adequate means to bring them back into such a condition that they can be operated upon if necessary.

All casualty clearing stations, no matter where situated, have now very large operation accommodation, all of them have space enough to set up three tables at least. Every attempt has been made to provide long wooden huts for the theatres where there is a good light and where an adequate temperature can be maintained. These theatres are adequately furnished with all the appliances which are necessary for the performance of the operations which have to be done in such units. The staff varies according to the work it is called upon to do. The staff in pressure times may be three times the normal establishment, not only in medical officers, but in nurses.

The casualty clearing station has to be put in such a place that it can be easily reached by the ambulance cars and so arranged that the cars can be passed back on a different road from that on which they came or by a road which allows of a double line of traffic. It is either on or near a railway, and by far the best arrangement is where it has a siding on which an ambulance train can stand to which the patients can be transferred by hand carriage straight from the tents to the train. This ideal, however, is not always obtainable, and then the wounded have to be taken by ambulance car to the railhead. This of course means more labour for the personnel and more jolting for the patient.

Relative Frequency of Abdominal Wounds.

Stevenson says in recent wars 15 per cent. of the wounded are hit in the abdomen and about 4 per cent. reach hospital. In the Spanish American War the percentage of abdominal wounds to total wounds was 2·6 per cent. In this present war the actual number of abdominal wounds will never be known, nor is it particularly important.

The number of abdominal wounds admitted to the field ambulance and casualty clearing stations are, subject to certain errors, known. The error is caused by the impossibility of accurately diagnosing the perforating abdominal wound. Since the onset of the operative treatment the error of course has diminished. The numbers as a matter of fact vary with each observer, and a surgeon who believes in the expectant treatment will be inclined to reckon as perforating those wounds which a believer in the operative treatment would place as non-perforating. The following figures were taken in certain casualty clearing stations by careful observation of the [illegible] of [illegible] perforations during a period in which the expectant treatment was paramount:—

Percentage of [illegible] Wounds to Total Wounds.

[illegible] = [illegible] per cent. | [illegible] = 0·7[illegible] per cent.
[illegible] = 1 [illegible] | [illegible] = 0·62 "

If we take the statistics from nine field ambulances and certain casualty clearing stations over a period of six months we get the following figures:—

The Percentage of Abdominal Wounds to Total Wounds.

Field ambulances	...	1·92 per cent.
Casualty clearing stations	...	0·72 "

The difference between the figures in the field ambulance and casualty clearing station is accounted for in the following manner:—

1. The field ambulance will naturally and rightly err on the side of making the graver diagnosis.
2. The mortality was high in the field ambulances, so that fewer cases reached the casualty clearing station.
3. At the casualty clearing station a more careful diagnosis will act in two ways: (1) It will include some buttock, chest, back, and thigh wounds as abdominal wounds; (2) it will exclude many cases of wounds of parietes. On the whole the effect will be to lessen the proportion of abdominal wounds to total wounds.

From these figures, which must be considered only approximate, the important facts stand out—namely, the relatively small number of abdominal wounds that a surgeon is called upon to treat, certainly under 2 per cent. of all wounded. The moral to be drawn is that one must not be led away by one's interest in abdominal wounds to spend more time and attention on them to the prejudice of the far larger number of wounds of a different part of the body. We must constantly bear in mind that all arrangements must be made so that the greatest good is done to the greatest number. If the number of medical men were unlimited this would not apply, but with a limited number of surgeons the best possible use must be made of their services.

Method of Recording Cases.

This paper is based on all abdominal wounds which reached an operating hospital from a certain sector of the line over a period of 18 months. In arriving at a conclusion of the mortality of abdominal wounds and what can be done for them by operative treatment it is necessary to take a sector of the line and to include all the cases, no matter at what hospital they are treated. Results do differ in different hospitals more or less depending upon their distance from the firing line; they will also differ according to the nature of the fighting. Again, if times are quiet there is plenty of time to treat adequately and deliberately all cases. At another time, when active operations are in progress, it may be only possible to pay attention to the most favourable cases. It is also necessary not only to reckon your operative mortality but also to bring into account all cases which arrive too bad for operation. This has been done in the present series. In the case of the moribund cases we have their numbers, but we do not in every case possess details of the injury. The statistics were collected in the following way. Every hospital which was called upon to treat abdominal cases was provided with a book in which certain headings were written down and filled in at the time of operation by the medical officers. In the early days these books were Admission and Discharge Books altered for the purpose. Later on, by the kindness of the Medical Research Committee, we have had supplied books provided with adequate headings which could be quickly and accurately filled in.

Comparative Mortality of the Casualty Clearing Stations and Abdominal Hospitals.

The following figures show the differences in results which may be obtained in different hospitals under different conditions and the necessity of including them all in your statistics if you wish to obtain an accurate result.

The following are the total mortality at four different hospitals during the same battle:—

(1) A casualty clearing station ... ... 54 per cent.
(2) An advanced operating hospital ... ... 30·35 "
(3) An advanced operating hospital ... ... 82·6 "
(4) A casualty clearing station ... ... 72·73 "

(1) A forward casualty clearing station.
(2) Was never pressed. (Mortality here during 7 months was 5[illegible].)
(3) Very heavily worked; many cases arrived late.
(4) A back area casualty clearing station.

Time Factor.

The table below was compiled by dividing the time between the receipt of the wound and the performance of the operation into two-hourly periods and noting whether cases were sent to the base or succumbed to their injuries It mainly shows two things (1) it gives some idea of the time in which cases are got out of the trenches and submitted to operation, and (2) it also shows the effect on the mortality of the time which has elapsed between the receipt of the injury and the performance of the operation It will be seen that most cases arrive some time between 6 and 10 hours after receipt of the injury If over 12 hours the mortality mounts, above 24 hours it appears that there is very little hope of getting a good result

TABLE I —*Effect of Time on Mortality*

Hrs	-2		-4		-6		-8		-10		-12		-14		-16		-18		-20		-22		24+

72	Colon	3	Colon

To the table have been added a few cases in which patients have died after an unexpectedly short period and also those in which recovery has followed the elapse of a long period between the receipt of the wound and the operation So far the limit of successful cases has been 36 hours for a resection of the small intestine and 36 hours for a suture of the colon

WHERE TO OPERATE ON ABDOMINAL CASES.

From the operative point of view the sooner the patient is submitted to operation the better From a post-operative point of view it is desirable to do the operation in some place where the patient can be kept quiet and properly nursed It will be seen that for very obvious reasons it is not possible to satisfy both conditions If you were to operate on a patient at the very earliest possible moment it would be in some place where the nursing was bound to be of a very primitive nature It would also have to be in some place which is exposed to shell fire Now, shell fire has a very bad effect on patients, and men who are well nigh careless of its effects when active and in good health are very much upset by it when lying passive in bed Again, you cannot well keep your sisters in such places although on many occasions they have done magnificent work under conditions of this kind Then, again you must consider the greatest good for the greatest number—one must do what is best for the majority The setting out on a large scale of the special advance hospitals means the dissipation of personnel, and medical officers, orderlies and nursing sisters are none too numerous for the work they have to perform Then, again, if you have special hospitals you have to have special arrangements for evacuation It may be stated that the best place for a casualty clearing station is some 10,000 yards behind the line on a railway or canal with good roads leading to it Taking it all in all this is the best place for abdominal surgery Remember that most of the time in getting a patient to an operating centre is spent within the trench system, the road journey is short, and although there will be some shaking in a motor ambulance it will be a good deal less than the patient has already experienced during the period of hand carriage If a patient arrives at a casualty clearing station 10 hours after the receipt of a wound it will most probably be found that only 60 minutes have been spent in traversing the distance from the trench system to the casualty clearing station.

It may be well to say here something about the mobile operating vans They have loomed somewhat largely in the public mind and have been a good deal discussed The idea is that you can have the motor van fitted out as an operating room, and that such a van should seek the patient rather than that the patient should be brought to the theatre. It may be stated at once that this idea is impracticable, and much more time would be spent in getting to the patient than is now spent in getting the patient to an ordinary clearing station When speaking of a mobile hospital van it must be understood that one does not include in this category a theatre which can be rapidly erected, adequately warmed and lighted, such as the French have made use of on many occasions, such units are only meant to be mobile in much the same degree as the casualty clearing stations are mobile On the other hand, special hospitals are very good under certain conditions In the Army to which I am attached Surgeon General Macpherson established two such hospitals and Surgeon General Pike another, and I will briefly describe them

The first one, which we will call No 6, was situated in a bleaching mill, it was about 5000 yards behind the firing line and took all the abdominal wounded of a certain corps It was formed by sending an operating surgeon and an anæsthetist and four nursing sisters to supplement the personnel of a field ambulance which was situated in this building It had a very good theatre and a large ward, which in cold weather was steam heated The evacuation arrangements were under the care of Colonel B M Skinner, the D D M S of the corps, to whose energy its success was greatly due Here we got cases frequently within two hours or less, the patients being carried straight from the spot where they were wounded to the hospital, irrespective of what division they belonged to This hospital was never pressed and never had the strain of a large fight placed upon it It continued to do its good work until the enemy began to pay attention to a bridge which crossed a canal on whose banks the mill was situated Then it was shifted a bit to one side and to another building which was much less commodious There it remained until the area passed out of the jurisdiction of the Army The sisters and operating surgeon and anæsthetist were then moved to a different part of the line and were re established in the ugliest château it has been my misfortune to see It was situated about 9000 yards behind the line and in a very much more difficult sector as far as evacuation was concerned Here it continued to do excellent work, although the railhead and a coal mine near by were continually shelled, many of the shells coming into the garden uncomfortably close to the house It was closed at last, as a casualty clearing station was opened near by Strange to say the day on which it was closed was the last day on which the place was shelled This hospital was also never pressed and the results, as in the last, were very good

The third hospital was opened in a field ambulance just before the onset of a big battle, and it was arranged that all the abdominal wounded from a corps should be brought to it As a matter of fact, in the stress of battle the wounded from two corps were carried to it The result was that the place was heavily worked and the results were not so good as in the last two

I will mention a fourth abdominal hospital, although it was not in the army to which I am attached, because there are some lessons which can be learnt from it Experience had been gained by the overwork of the last hospital and adequate arrangements were made to prevent it in future The personnel of this particular hospital was adequate for its needs In addition, it was arranged that when the hospital became full the wounded should be sent on to a casualty clearing station situated somewhere farther back The result of this arrangement was that all the abdominals that had the good fortune to be admitted were well and rapidly treated

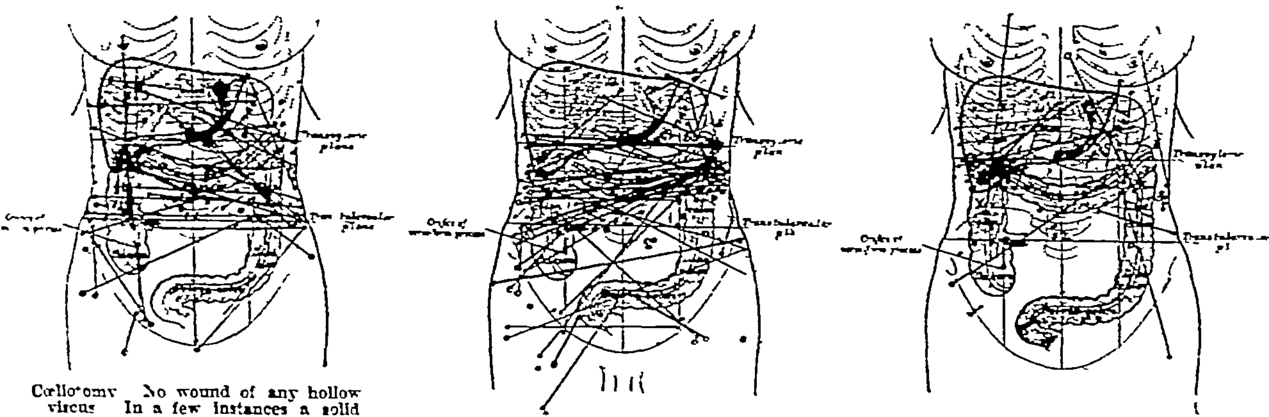
The lesson to be learnt from the experience gained at such hospitals can, I think, be summarised as follows That in quiet times such hospitals opened at field ambulances by the provision of an operating surgeon and a few sisters can do magnificent work and save life If, on the other hand, such hospitals are to be opened in times of battle, it is necessary to have very much the same personnel that is allowed by the establishment of a casualty clearing station

ARRANGEMENTS AT THE PRESENT TIME IN THE FRENCH AND BELGIAN ARMIES

It has been said above that the French and Belgians went through the same experience as ourselves As the line became fixed, operation became the established practice The French have established advance abdominal hospitals

Charts showing the General Incidence of Fatal and Non fatal Gun shot Wounds of the Abdomen

FIG 1. FIG 2. FIG 3



Cœliotomy No wound of any hollow viscus In a few instances a solid organ was hit

No operation Died

No operation Recovered.

These charts were made by indicating an anterior wound by a black mark, a posterior wound by a circle and joining the two when they represented the entrance and exit wounds of a missile

by means of what they call *motor surgical ambulances*, these are really hutted theatres which can be easily erected, and they are really extremely complete in their arrangements These hospitals are pushed rather further forward than is the practice in the British Army and have, I believe, met with a large measure of success

Professor Tuffier also informs me that the French have established dug out operating centres situated some hundreds of metres behind the trenches, where it is possible to operate on the wounded in from a half to two hours after the accident He adds—which is of considerable interest—that with the very large attacks they have had and the great number of wounded they have had to be dealt with, this arrangement has not given very good results, for the reason that the wounded have arrived late, and very often these ambulances have been unable to deal with the numbers of wounded they have received.

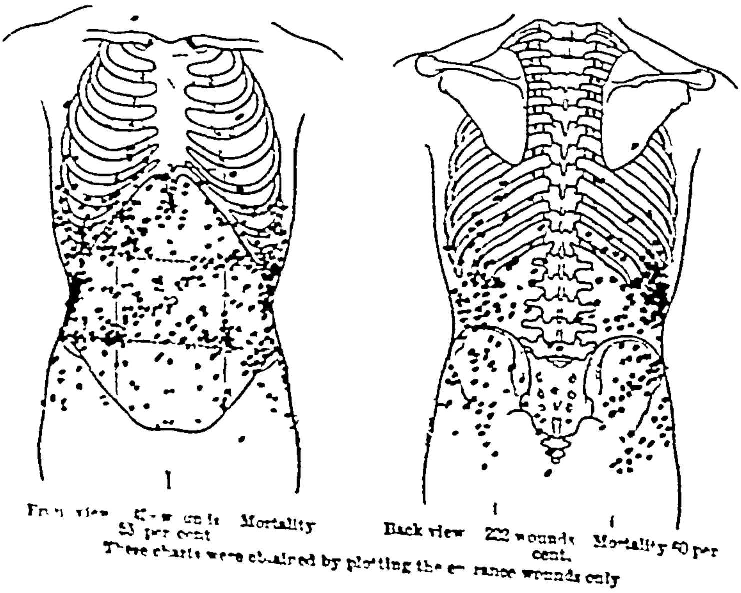
The Belgians have followed suit to a certain degree and have pushed their abdominal operating centres far forward and have lately provided special ambulances for the transmission of the operated man to the hospitals farther back I have not so far ascertained what measures of success they have had but the Belgians are favourably situated in that they have large base hospitals very close behind the firing line

NATURE OF PROJECTILES THAT CAUSE THE WOUNDS

Bullets —There are very many different kinds of bullets used in this war and apparently their number goes on increasing As is well known the standard English French, and German bullet is a pointed one The English and German is a composite projectile which is liable to break up into mantle and core The French bullet is much longer than either of the above and is made of solid copper alloy Although not liable to break up it is liable to very great distortion Naturally we are mostly concerned with the German projectile which as a rule is pointed but sometimes the old ogival headed bullet has been extracted from wounds All the modern pointed bullets are more unstable than the bullets of the Boer War The instability is said to be most marked at the beginning and the end of the flight Again, in this war, where the fight takes place amongst houses, there are many opportunities for the bullet to be deformed and deflected Again the velocity and stability of a bullet is largely affected by passing through sandbags or a parapet, which, as a matter of fact, has to be something like 4 feet thick to be bullet-proof. There is plenty of proof that, whether from inherent instability or from hitting some object, the bullet does spin, and in several cases a bruised impress has been seen on the skin which could only have been made by a sidelong impact of the bullet Again, in those cases where two legs have been wounded by the same bullet the first leg has been perforated by a small standard track and the opposite leg has suffered a large gaping wound, the obvious explanation being that the bullet in passing through the first limb was made to *spin* and so caused a more extensive wound on the opposite member A good deal has been heard about the explosive effect of the modern pointed bullet, and although one may say that it does cause worse wounds than the ogival-headed projectile, I am by no means persuaded that its so-called explosive effect is anything but a very rare occurrence I am strengthened in this opinion by the study of accidental wounds, of which one sees a great number Men are shot at all sorts of close ranges up to actual contact and yet unless a hard bone is touched it is not usual to get the explosive type of wound

Charts showing the Regional Incidence of Wounds

FIG A FIG B



Front view [illegible] wounds Mortality 53 per cent

Back view 222 wounds Mortality 60 per cent.

These charts were obtained by plotting the entrance wounds only

Shell fragments —These are of course, of all sizes, but the fragments which are the cause of the abdominal wounds that the surgeon is called to treat are generally not more than 1¼ inches in the greatest diameter, usually a good deal smaller There are different kinds of shells used, and some importance may be attached to the nature of the shell by which the man is wounded

High-explosive shells —These shells may burst in the air, on contact with the ground or after they have impacted themselves deeply in the earth The velocity of the fragments into which the shell is blown depends on the disruptive charge, and the fragments under such a condition fly out in all directions The shape of the fragments depends largely on the type of shell—if the shell is segmented the pieces are more or less quadrilateral, if not segmented they have extremely sharp and ragged edges Such shells, bursting on the ground, naturally become covered with dirt

Shrapnel—These shells usually burst in the air with a time fuse They are of all sizes and the leaden balls with which they are filled also vary somewhat in size The penetrating power of such balls is due tó the remaining velocity of the shell The direction of the shrapnel balls will, as a rule be downwards In some cases apparently a shell is of a combined high explosive and shrapnel type

Bombs and grenades—In the early part of the war these bombs were often extemporised and consisted of tin boxes filled with an explosive, scrap iron cobblers' nails, and screws &c Now a days they are made of iron, the surface of which is marked with grooves, so that on explosion they break up into quadrilateral fragments Sometimes the force of the explosive will cause a bomb to burst into smaller fragments so that often they are no bigger than a big match head These fragments, although small, have apparently from their high velocity, a very great penetrating power in the immediate neighbourhood of the explosion, although this is rapidly lost as the distance increases

Trench mortars—These are of various shapes, but consist essentially of a very large high explosive charge with a comparatively thin containing envelope, they therefore burst very often into large ragged fragments as well as minute ones They are generally timed to burst either on the ground or in the ground

Bayonet wounds—These are very seldom met with, being usually fatal on the field Mention may be made of two cases In the first the bayonet penetrated the man's back and came out by his umbilicus No viscus was injured and the man succumbed to hæmorrhage The second was the case of a man who was late in answering a challenge and was bayoneted by the sentry The bayonet entered the left hypochondrium and wounded the stomach near the greater curvature and entered the back wall of the abdomen Though promptly operated on he died, not of his stomach wound but of retro peritoneal sepsis

RELATIVE NUMBER OF DIFFERENT PROJECTILES AND THE PROPORTION RETAINED

Table II has been drawn up with the intention of giving some idea of the relative frequency of the different projectiles met with in abdominal wounds, it also shows the relative number retained in the body Now this table must be taken as only relative for several reasons In the first place it is often impossible for a man to tell what hit him In the second place one cannot always be sure from a study of the entrance and exit wounds what was the nature of the projectile, and again, many do not differentiate between high explosive shell and shrapnel, the soldier generally including most shells which are not of a large calibre under the name of shrapnel As a matter of fact, there is very little difference in the nature of the fragments in high explosive shells, bombs, rifle grenades or trench mortars if one excludes the larger fragments with which we are very little concerned

TABLE II

Bullet		Shell fragment		Shrapnel		*Bomb or grenade*	
Out	Retained	Out	Retained	Out	Retained	Out.	Retained
181	103	24	151	10	62	6	82
284		175		62		88	

Bullets—Bullets and high explosive shells furnish a large proportion of abdominal wounds More bullets pass through the body than other projectiles The reason for this is obvious The causes for retention are not so obvious, and I have known bullets fired at a comparatively short distance remain within the body In other cases the bullet may have passed through the earth and so have had its velocity diminished Ricochets account for a certain number

Shells—These show a high proportion of retention This is obviously due to the shape of the fragments Shrapnel shows a large proportion, and this is no doubt due to the small velocity and round shape

Bombs and grenades—The retained fragments are strikingly in excess of those passed out The large proportion of retained fragments at once suggests the possibility of armour, and no doubt armour could be devised which would keep out many fragments It really is more or less a question of what the soldier is able to carry One cannot help being struck with the resistive power of an ordinary book, as one has often seen projectiles arrested by such articles when carried by the soldier The great saving of life produced by the steel helmet makes one hope that something could be produced which would be equally efficacious in protecting the body Although we could not expect such shields to be supportable and bullet proof yet the number of passed out bullets is far out numbered by the number of retained bullets, shell, and bomb fragments which possess far less penetrative power

RELATIVE MORTALITY OF THE DIFFERENT PROJECTILES

TABLE III

Bullet		Shell fragment		Shrapnel		Bombs or grenades	
To base	Died.	To base	Died	To base	Died	To base	Died
60	63	46	68	10	21	30	31

There is nothing very much to be learnt from this table except that bullets are as dangerous as other projectiles and that bombs and grenades seem to be the least noxious

---

THE IMPORTANCE OF

THE DIAGNOSIS OF ENTERIC FEVERS BY AGGLUTININ DETERMINATIONS

BY E W AINLEY WALKER, M A, D M OXON,
CAPTAIN O T C UNIV OXON FELLOW AND TUTOR OF UNIVERSITY COLLEGE AND LECTURER IN PATHOLOGY IN THE UNIVERSITY OF OXFORD

(*Report to the Medical Research Committee*)

IN the course of recent criticisms directed to this subject several points of interest have been raised, and some misapprehensions have become evident which it may be of advantage to consider briefly They are dealt with in the order of their publication

I —In a discussion on "The Technique of the Agglutinin Test" Dr P N Panton[1] strongly dissents from my contention that "the microscopic method entirely fails *to give comparable quantitative measures of the titre of a patient's serum on successive occasions*" He considers the microscopic technique commonly employed to be fully adequate for this purpose In defence of this view he expresses certain opinions regarding the constancy of the materials employed, the general accuracy of the microscopic technique and other matters whose validity ought not to pass unchallenged Yet merely to deny Dr Panton's statements categorically would not assist in illuminating the subject, while to explain in detail *ab initio* the reasons why they are misleading would require not only a repetition, but also a *considerable* amplification of my previous Note[2] *For he places* one in this dilemma that he makes *statements* contradictory of well established *evidence much* of it old and quite familiar, but at the *same time* he *omits* to adduce any experimental data in support of his position, such as could be submitted to critical analysis In some cases he seems actually to be unaware of the factors which militate against accurate quantitative results in the *performance* of agglutination tests For example, he *still* (so far as one can judge) makes the *successive* dilutions of a serum by adding more and *more* bacillary suspension, in apparent unconsciousness of the effects of the mass influence *of bacteria on* the absorption of agglutinins These *effects* however *are* such as to render it essential that the serum whatever its dilution, shall always operate on equal masses of bacteria if accurately quantitative *observations* are desired Fortunately many of *Dr Panton's* arguments have already been admirably dealt with by Glynn[3] It may therefore suffice upon the present occasion to meet his contentions regarding the value of the microscopic method for the purpose under discussion by examining its performance in the only direction in which he has brought forward definite experimental evidence These observations of his own afford very valuable information For though he himself interpreted them guardedly as evidence in favour of the exploded theory that in inoculated persons any febrile condition of a certain duration causes or may cause, disappearance of the inoculation agglutinins they serve in reality quite a different purpose They prove to demonstration that the microscopic method as employed by him cannot for accuracy and reliability support any comparison with results obtained by the use of Dreyer s macroscopic technique Indeed his figures show that the results obtained by the microscopic method, even as regards the mere detection of agglutinins without considering the question of their measurement, are very much worse than one would have ventured to suggest was probable had these data not been supplied. The results of typhoid agglutination tests are recorded by Dr Panton for 72 out of 100 consecutive cases in inoculated individuals who had suffered from various febrile conditions They are tabulated below alongside the results for the first 100 similar cases examined by myself by Dreyer s method

Cases examined by the microscopic method (Panton)		Cases examined by Dreyer s method (Ainley Walker)	
Typhoid agglutination.	Per cent	Typhoid agglutination.	Per cent
"Completely negative"	62	"Nil, 1 in 25	0
"Negative or partial."	16 7	"Standard " or trace 1 in 25.	3
"Positive."	20 8	"Standard," 1 in 50 or more.	97

By Dreyer s method every case showed measurable quantities of agglutinin in 1 in 25 dilution of the serum, and 97 per cent showed marked agglutination visible to the naked eye in at least 1 in 50 and frequently in very much higher dilutions But in the cases examined by Dr Panton by the microscopic method the test was "completely negative" in nearly two-thirds and "positive" in only about 21 per cent Nothing could be more convincing as regards the relative delicacy reliability, and general accuracy of the two methods for the detection of agglutinins A fuller justification could indeed hardly be found for my criticisms of the microscopic method than that here provided by Dr Panton s own observations

II —In a letter to the Editor of THE LANCET Captain R P Garrow[4] makes some interesting comments on my recent "Illustrations of the Diagnostic Value of Agglutinin Determinations"[5] And one may certainly be permitted to endorse his plea for judgment and caution in the interpretation of the results of agglutination tests particular regard being had to the methods employed Probably we are much more nearly in agreement than the incisive character of some of his expressions might suggest. But in charging me with ignoring clinical observation as a means of diagnosis in enteric fevers he misunderstands me My article was not concerned to discuss the clinical diagnosis of enteric fevers To do so would be quite beyond my province The point which it was desired to emphasise is that when and wherever these infections are abroad many mild and atypical cases may occur which are *not capable* of diagnosis by clinical observation alone Moreover in every case the differential diagnosis between typhoid, paratyphoid A and paratyphoid B still rests and is likely to remain with the pathologist The cases charted in my article purposely included a number of such mild or atypical attacks And the fact that among the mass of cases which receive the provisional diagnosis pyrexia of uncertain origin cases of enteric fever may be numerous and important that they form a grave source of danger and that the agglutination test (even as commonly applied) affords the best criterion for their diagnosis is emphasised by competent authority as follows (all italics mine) —

> [illegible] Typhoid Fever [illegible] is an exceedingly [illegible] group especially [illegible] The cas may be divided into two classes, the first including those characterised by a mild and short course the other those in which despite the short course the onset is severe .....*In many instances these mild forms are taken for malaria* mountain fever &c., while doubtless they are not uncommonly put down as *febricula* ... The recognition of this group comes through one of two ways They may show characteristic signs ... *or be recognised only through the routine Widal reaction* .. ..We are not sufficiently impressed with the importance of this group. Keeping their frequency in mind, the physician will watch more closely *and have the agglutination reaction tried more frequently* in patients with mild fever ...... *For the community the recognition of this group is most important* .... "

If the foregoing statements were valid before the introduction of protective inoculation much more are they so in relation to the character of enteric infections in inoculated persons, among whom the relative proportion of mild, abortive, and atypical attacks will naturally be higher than among non inoculated individuals Thus it appears that in urging the importance of relying on agglutination tests for diagnosis in such cases one is not guilty of ignoring clinical observation, but can claim the strong support of clinical teaching

That the facts thus indicated were quite fully recognised by experienced observers who have worked upon the epidemiology of enteric infections is illustrated in the subjoined quotations from an article by Grattan and Wood[6] on paratyphoid fever in India, where the case is stated plainly and with great cogency

> In the first place owing to the mildness of the disease in some instances patients are not diagnosed paratyphoid but influenza, tonsillitis, pyrexia of uncertain origin rheumatism or pneumonia, with the result that they are sent out of hospital within a few weeks of going sick and may return to barracks while still infectious. In the second place such convalescents are frequently sent with other debilitated men to the hills during the hot weather and thus the hill stations where men of several corps mix together may serve as distributing centres of the disease. Furthermore, the ambulant case is in reality ..... "
>
> An epidemic is started from one acute carrier the nature of whose illness is not recognised owing to its mildness He infects other men, some of whom are recognised as cases of paratyphoid others again, are not diagnosed, and possibly others never report sick at all. These men soon return to barracks and come in contact with other men in soldiers homes, &c. and though probably only infectious for a few days manage thus to disseminate the disease "

With regard to the interpretation of agglutination results Captain Garrow expresses so clearly exactly what ought to be done in carrying out an investigation of this problem that his terms may well be quoted (italics partly mine) —

> ... blood culture should be performed at once .... Whatever the result of the blood culture, agglutination tests by a strictly quantitative method should be performed and repeated at suitable intervals. ... The object of this procedure in a case in which an absolute diagnosis by blood culture has been obtained is ..... to furnish *agglutination results controlled by blood culture The data so obtained are essential as a guide to the interpretation of agglutination results in other cases* in which blood culture has failed to give a diagnosis .... "

But Captain Garrow appears to have overlooked the fact that this fundamental work is precisely what has already been done on a very considerable scale And there comes a time in the conduct of investigation when the evidence accumulated seems to be sufficient to convince observers that the guide thus obtained may be relied upon, and that the problem may in certain aspects be regarded as solved Now the evidence obtained by Dreyer[7] and his co-workers in very long series of cases is that *in every case* bacteriologically proved to be typhoid or paratyphoid B, and also in similar cases of paratyphoid A (since the low level of agglutinin titre found even at the maximum in many cases of this infection was fully recognised), the diagnosis independently arrived at by means of agglutination tests carried out by Dreyer s method was *proved* to be correct Results of such a character may fairly be termed a *uniformly accurate diagnosis* They would seem to justify my statement—not in the extravagant interpretation placed on it by Captain Garrow "that agglutination tests alone *invariably* furnish an *absolutely infallible* diagnosis"—but in the form in which it was made and with the limitations carefully specified in the article that such tests " can be made to yield a uniformly accurate diagnosis in cases examined during active infection " The limitations specified and repeated from a previous article by Dreyer and myself[8] were that a diagnosis should not be based on a rise of titre of only 100 or 200 per cent if it is clear that the maximum of that rise falls markedly outside the period sixteenth to twenty fourth day of the disease We further stated that so far as experience at present goes if a regular rise and subsequent fall even of only 100 or 200 per cent occurs in the typhoid (or paratyphoid) agglutinin titre of the serum and its maximum clearly falls between the sixteenth and twenty fourth day from the onset of illness, the case is likely to be one of typhoid (or paratyphoid) infection It would be prudent, therefore, that it should be so regarded under present conditions, when the circumstances are such that it is a prime object to prevent the escape of undetected carriers For every case that is missed is a potential carrier of infection

Captain Garrow further takes exception to my use of the graphic method in joining successive points on the charts of agglutinin titre by *curved* lines, which he terms "figments of imagination" Here he is rather led astray by a telling phrase It is, of course, in one sense never possible to do more than speculate (more or less logically) regarding the course of nature between points of observation One was therefore careful to speak guardedly of these interpolations as "curved dotted lines *to indicate approximately the probable form* of the agglutinin curve" But it is surprising that Captain Garrow should express a desire to see the points jointed by *straight* lines For a little more consideration would have shown him that such straight lines would not only equally be figments of imagination, but they would also be deliberately *misleading* If there is one fact more than another that has been firmly established for years, it is that both the rise and fall in the agglutinin titre of the serum follow *curves* Why, then, draw straight lines if one wants to illustrate what one thinks is probably occurring between points of observation?

To turn briefly for a moment from the general to the more particular Captain Garrow very properly draws attention to a bad slip of the pen in a recent article by Professor Dreyer and myself in stating the maximum of a curve lies between the two highest readings, when we should have said on one side or other of the highest reading But, as he notes, the correct principle is followed in my charts In reference to Chart 6, in which the T estimations exhibit a progressive fall, the reason why a maximum is placed between the first two readings is that, as can be seen at once by plotting out on a large scale, a smooth curve through the last five points will not pass through the first Incidentally, this shows how information is gained from the use of *curved* lines of interpolation In Chart 10 the reason for the diagnosis "clearly a case of B infection" is given in the letterpress attached, if read in conjunction with the whole of note 3

Case 4 of my article receives some special criticism In publishing this chart attention was drawn to the fact that the case had "simulated a tertian ague" It was selected for publication partly to illustrate the fact (see Osler and McCrae above) that such cases may be *mistaken for malaria* The clinical data given were a headache, a shivering fit accompanying the first sharp rise of temperature, and two more sharp rises of temperature on the third and fifth day (though without definite chills) The blood was examined for malarial parasites, but none were found, and a *typical typhoid agglutinin reaction was observed*, as shown in the chart On this evidence Captain Garrow regards the case as one of malaria, but it is quite impossible to assent to such a diagnosis The patient came from the Mediterranean area, where he had had prolonged fever, associated with severe intestinal disturbance, and he appears to have suffered at any rate, from paratyphoid A and paratyphoid B infections (mixed or consecutive, *vide* chart) There was no indication of malaria in his history, and he had been three months in England when he was seized with the brief pyrexial attack under discussion and developed an extremely characteristic typhoid agglutinin reaction of moderate grade Captain Garrow writes in a way that might convey the impression that he supposes every brief tertian periodicity of pyrexia with a chill at the onset to be necessarily of malarial origin But he is, of course, aware that this is not the case Repeated chills may occur, with or without marked periodicity, in various stages of enteric fever (to go no further afield) *vide* Osler and McCrae, loc cit, p 115, where a chart of enteric fever is given, *showing seven successive periodic chills* (cp also Osler and McCrae, p 105, and Allbutt and Rolleston's "System of Medicine," 1905, vol i, p 1108 and p 1132)

III —Captain H Graeme Gibson's letter in THE LANCET of Jan. 13th, 1917 (p 78), follows quite a different line of criticism In effect the letter pointedly suggests that Dreyer, Ainley Walker, and A G Gibson have ignored or are ignorant of (it is not clear which is intended) certain earlier work, which had proved long before the same facts as they imagine themselves to have established more recently In doing so it, of course, tacitly admits that the facts in question have become established, and on this account its appearance marks an important stage in the gradual crystallisation of opinion regarding the diagnostic value to be attached to systematically repeated and (exact agglutinin determinations But Captain H G Gibson is entirely mistaken in his conclusions

Medical science is deeply indebted in very many directions to the admirable studies carried out by officers of the Royal Army Medical Corps, and it is a matter of particular regret to the present writer that he is compelled—not, be it noted, by any claim or action on the part of authors themselves, but by the misleading charges advanced (however disinterestedly) by Captain H G Gibson — to bring under criticism work which constituted at the time a valuable and successful endeavour to advance knowledge in regard to enteric infections, particularly in the domain of epidemiology This task, which is not undertaken lightly, is rendered personally somewhat less repugnant by the fact that, whatever share may be assigned to his co-workers, any results which may have been attained by the Oxford School of Pathology are pre-eminently due to the scientific insight and experience of my friend and colleague Major Dreyer now absent on active service

The statements contained in Captain H G Gibson's letter may now be dealt with Dreyer, Ainley Walker, and A G Gibson did not ignore the earlier work referred to

1 There is no suggestion in any of the authorities whom Captain H G Gibson quotes either of the need for accurately quantitative measurement of agglutinin titre, or of a technique and materials by means of which such measurements could be made

2 Nor is there either the statement, or the evidence to prove it, that reliable diagnostic data can be secured by the systematic repetition of exact agglutinin determinations at appropriate intervals—three to five (or more) successive determinations at intervals of from three to five days

3 The curves reproduced by Captain H G Gibson marked no new departure in pathological investigation For accurately determined curves of agglutinin titre had been published, at any rate since 1902, by Madsen and Jörgensen, Dreyer and Schroeder, Widal, Dreyer and Ainley Walker, and others, before the appearance of the communications referred to, and were presented in greater detail and with more exacitude

4 The problem of the diagnosis of enteric fevers in inoculated men by means of agglutination tests became important in India and elsewhere from the period of the re introduction of typhoid inoculation in the Army in 1905, but it remained unsolved, although the key to its solution had been provided in the work of Madsen and others just mentioned and in the improvements in technique devised by Madsen and by Dreyer

5 As regards the observations of Grattan and Harvey[10] and Grattan and Wood *we made reference to them* where they were germane to the purpose in terms of which the opening sentence ran as follows" —

> "It is in absolute agreement with the important and careful observations carried out by Grattan and Harvey, and Grattan and Wood some years ago in their investigation of paratyphoid fever in India."

6 As concerns the quotations taken from reports on the enteric fever depôt at Naini Tal, they do not represent the views which we maintain. Had we referred to them it could only have been to express our very strong dissent from a number of their conclusions—for example

Naini Tal Reports	*Comment*
In paratyphoid fever the Widal reaction is *invariably* raised for the *B typhosus*"	It is not *invariably* raised
"In all cases of fever in inoculated men the blood should be taken *near the beginning* and *towards the end* of the fever If the two results are the same the case is probably not enteric."	This is not necessarily true for a marked rise and fall in titre may have occurred between two such distant determinations We regard three determinations as the normal minimum And we should consider it quite deplorable to wait until towards the end of the attack before attempting to secure a diagnosis.

In opening his criticism Captain Gibson takes exception to a statement of ours which offered a very moderate presentation of the facts existing at the time when it was written (December, 1914). He states that since 1905 repeated observations of the serum agglutinin content taught at the Royal Army Medical College "*and carried out* by Army bacteriologists" But the first sentence of his own quotation from the Naini Tal reports throws an interesting light upon the latter claim, and in itself goes far to justify our statement

Statement by Dreyer Ainley Walker and Gibson	*Naini Tal Report.*
It is probable that the absence of accurate diagnosis in the past explains the fact that statistical results arrived at in our Army have *not always* been so convincing as would otherwise have been the case "	"Some of these *errors in diagnosis* are due to the fact that the men had been inoculated and therefore their blood gave a positive Widal reaction and they were *diagnosed enteric fever on the strength of this alone* "

Captain Gibson then proceeded to urge that—

> The necessity for using Dreyer's technique is not apparent, and equally reliable results can be and have been obtained when using *living* suspension of bacilli *provided the suspension is standardised* "

This shows that the writer has failed to understand what is meant by *standardisation of the agglutinability* of a bacterial suspension The standardisation of the agglutinability of living suspensions is no doubt theoretically possible, but for any practical and routine purpose it is quite out of the question Indeed, one is almost driven to the hardly credible conclusion that, with Dr Panton, Captain Gibson supposes the determination of a given opacity or number of bacilli present per c c. of the suspension to constitute the standardisation " of an agglutinable culture

At the end of the letter a case is stated against Dreyer in error, and with a degree of injustice which might have been avoided had the writer studied more attentively the authorities he quotes He points out that Grattan and Wood mentioned in 1910 the frequency of *low* titre of serum in paratyphoid A, and would appear to suggest that Dreyer was still ignorant of this fact in 1915, although Grattan, Dreyer and Wood had been working together This suggestion is based on Dreyer's statement that "for a considerable time I did not know *how low* is the agglutination given by paratyphoid A in certain cases " But the explanation lies in the meaning of the words "*how low*" and in their context Grattan and Harvey[10] found in 7 of their 8 cases "*low* dilutions (20 to 40), and always incomplete." Grattan and Wood[6] mentioned that they *had seen* cases where the agglutination did not reach 1 in 10 Their statement with regard to diagnosis in paratyphoid A is given below, along with the *context* of Captain Gibson's quotation from Dreyer

Grattan and Wood[6] *(1910)*	*Dreyer*[7] *(1915)*
a positive agglutination for this organism in a dilution of *1 in 10* is in our opinion *very strong evidence* of the nature of the patient's fever	One had always taken *1 in 25* as the limit below which no positive diagnosis should be made But in the case of paratyphoid A that is wrong If one uses standard cultures and follows the technique laid down for their employment, I am now convinced that an agglutination of *1 in 10* is for all practical purposes *diagnostic* in cases of paratyphoid A

This (1 in 10) was *the degree of lowness* of titre for positive diagnosis of which Dreyer (and everyone else) was previously unaware And no one had ever before suggested that paratyphoid A could be diagnosed with certainty (in non inoculated and T inoculated persons) on so low a titre So far was the fact from being already familiar that Leishman[11] was even then unable to accept it remarking with regard to this conclusion of Dreyer, "Personally I think he goes too far because of the very low dilutions to which he attaches importance ' Dreyer Grattan, and Wood worked in association for a considerable period, and ample time has passed since Dreyer's statement was made for Grattan and Wood themselves to have drawn attention to any infringement of their priority had such existed It can constitute no breach of confidence of any kind to state that Lieutenant-Colonel Grattan and Captain Wood were the first officers in the Royal Army Medical Corps to recognise fully the value of Dreyer's method and to make use of it consistently.

AN EASY AND RAPID METHOD OF

DETECTING PROTOZOAL CYSTS IN FÆCES BY MEANS OF WET-STAINED PREPARATIONS

BY ROBERT DONALDSON, M A, M B EDIN, F R C S EDIN, D P H

BACTERIOLOGICAL SPECIALIST WAR HOSPITALS READING PATHOLOGIST ROYAL BERKSHIRE HOSPITAL, READING ETC

IT is of the highest importance to single out from among those previously infected or exposed to infection the small but dangerous minority who form the little band of *histolytica* carriers This involves the expenditure of an enormous amount of time on the very necessary routine examination of all suspected fæces in order to detect the presence of protozoal cysts, more especially those of *Entamœba histolytica* To fix and stain films from each of the large number of specimens requiring examination is impracticable owing to the amount of time involved

The usual method of detection is to examine wet preparations, which is done, as a rule, in one of the two following ways Having determined the existence of cysts by their higher refractility in a wet film preparation of fæces in normal saline, another similar film is made in which, however, the saline is replaced by Gram's iodine This method obviously involves the making of two separate films In the alternative method the first step as above described is omitted, and only a wet Gram's iodine preparation examined The object in using iodine is to bring out sufficient detail—more particularly the nuclear structures—in order to differentiate between cysts of *Entamœba coli* and *histolytica* respectively

These methods are open to two important objections The first, involving as it does two separate preparations, takes up too much time In the second place, as the iodine in both methods stains the food débris more or less deeply, there is not sufficient colour contrast between the cyst and the débris surrounding it to enable it to be singled out rapidly and with certainty Where cysts are very few in number, even an expert at such examinations may miss the occasional cyst on which a diagnosis alone may rest, while those less expert must spend a considerable amount of time carefully scrutinising everything in the film, and even then will probably frequently be in error The lack of contrast in such preparations where there is so much similarly stained material to distract the eye, necessitates considerable concentration on the part of the observer, involving a greater expenditure of time and labour, and consequently allowing a greater loophole for error

In order to reduce the amount of time spent on such examinations to a minimum and to render it almost impossible for even a novice to fail to detect the presence of cysts, I have devised the following stain mixtures. After trying various proportions, it has been found that a mixture of equal parts of the two stains used in any of the three following combinations will yield the best results

A Five per cent aqueous solution of KI saturated with iodine to which is added an equal volume of either—

B (1) A saturated aqueous solution of rubin S, or
(2) A saturated aqueous solution of eosin, or
(3) Stephens's scarlet writing fluid

(*Note* —1 I have found it necessary to specify this particular brand of red ink as some brands are useless for the purpose 2. Basic fuchsin cannot be used)

A few loopfuls of one of the above stain combinations are placed on a clean slide, a loopful of fæces taken and rubbed up with the stain to form a fairly smooth suspension, and a clean cover slip gently lowered over the drop To get the best possible definition it cannot be emphasised too strongly that the film so made should spread out under the cover slip by capillarity so as to form the thinnest possible layer—preferably a layer which is no thicker than the diameter of a *coli* cyst. Obviously no gross particles must be left in the film, otherwise the cover slip will not lie flat The exact amount of stain to place on the slide will soon be learned after one or two attempts and will depend on the size of the platinum loop employed and the size of the cover slip It is also preferable, although not essential, to mix afresh for each day's use the two elements of the combination stain

I wish to point out that the way in which the film is made is a point of considerable importance, especially where rubin S or, to a less extent, eosin has been used in the combination , for if the layer of fluid between the slide and cover slip be too thick the superfluous film of fluid overlying the cyst tends to render the latter less bright In the case of cysts of the size and shape of *E coli* or *histolytica* this makes very little difference but if one is hunting specially for cysts of *Lamblia intestinalis*, and still more of *Tetramitus mesnili*, the colour contrast is not so marked owing to the smaller size of the cysts and the consequent thicker red layer of fluid overlying them Where the worker has not acquired sufficient dexterity in making such a film the difficulty may be got over by his using rubin S or eosin of only half saturation in the stain combination, or by employing the scarlet writing fluid above mentioned In this way the effect of the super imposed deeper red is to some extent obviated

Another point to be noted is that where pressure has been applied to the cover slip to cause the film to be spread out, many of the cysts, especially those of *Entamœba coli* will be seen stained red by the red element of the stain combination This is due to the fact that the cystic sphere is very easily ruptured, thus allowing the red stain to penetrate Close examination of such red cysts will invariably demonstrate some rupture in the continuity of the cyst wall, which, as long as it remains intact, prevents the penetration of the red dye Outside such cysts part of the contents or one or two nuclei can often be seen lying more or less closely apposed to the rupture While the vivid contrast between cyst and background is not so marked as in the case of non ruptured cysts it is nevertheless almost impossible to miss recognising them, as they stain a deeper tint of red than the surrounding background, while the nuclei are just as distinct and as easily demonstrated as in the unruptured cysts It is here not a question of the cyst being degenerated but merely of the healthy cyst being ruptured With the eosin or ink combination such a cyst stains a bright cherry red, while with the rubin S combination it is more of a terra cotta tint

In a wet preparation stained according to the above directions, there is a more or less homogeneous red background from which the cysts stand out as brilliant yellow or greenish yellow spheres which even the veriest tyro cannot miss seeing Such cysts have a very sharply defined outline which in the case of *coli* and *histolytica* cysts appears, in the rubin S combination, using daylight as the illumination, as a sharp deep purple ring In the case of other cysts this well recognised outline is not so deeply coloured although it is still tolerably sharp The nuclear structures in the cyst stand out as prominently as with the old simple iodine method Of course, where the light is too strong it may be necessary to close the iris diaphragm slightly to bring the nuclei into relief

The method of stain which I here recommend is not, I need hardly say a stain which will allow of a differentiation between cysts of *Entamœba coli* and *histolytica* respectively The various points which in doubtful cases must be considered before a definite opinion can be given must be gone over in specimens treated with the above stain combination equally as in the simple Gram films Where the examiner feels that it is necessary to measure the diameter of the cyst in order to differentiate between *E coli* and *histolytica* respectively the wall of these two types of cyst is so sharply defined and so prominent—as above mentioned—that with an eye piece micrometer measurement is easily and accurately made inasmuch as the halation seen in simple Gram stained preparations is completely eliminated

Although it is not pretended that the new stain combination can be definitely used as a means of distinguishing between cysts of *E coli* and *E histolytica* respectively, there are one or two points about the staining properties which, to one who has examined many specimens suggest the possibility of differentiation although I am not prepared to say at present that in every case these can be relied on solely In the case of cysts of *E coli* and *E histolytica* and of the so-called iodine bodies to take the cysts most likely to require differentiation there is to the practised eye a slight shade of difference in the colour tone of the first two as compared with that of the iodine body There is a less vivid colour in the case of *histolytica* as compared with *coli* which is the most brilliant object of all in the field with the exception of plant hairs With a low power the nuclei of *coli* cysts are easily seen as a rule while those of *histolytica* are less evident The iodine body appears less vivid than the *histolytica* cyst, probably partly by reason of the large iodine-stained masses which it contains Its luminosity is less Even with a low power, however, it is easy to differentiate the so-called iodine body from *histolytica* or *coli* cysts, inasmuch as the first-named shows a well-defined round body at one pole which stains a very intense brown colour Its outline is so sharply defined and its depth of colour so intense that it is easily differentiated from the immature *coli* or from the *histolytica* cyst, which happens to contain a vacuole which takes up the iodine stain Such a vacuole is rather diffuse, has no sharply marked outline, and is such a faint brown tint that its margins seem to shade off into the surrounding colour of the cyst Another point of difference between the so called iodine body and the cysts of *coli* and *histolytica* is that the outline of the first-named is not represented by such a definite and sharp deep purple line

There is an indication also of a slight difference between cysts of *coli* and *histolytica* respectively on close examination of the contents Cysts of the latter type seem to present a slightly more granular appearance than those of *coli* This lessened granularity in *coli* cysts may partly account for their extremely vivid brilliance In this connexion it is interesting to note that the granularity of the so-called iodine bodies appears to resemble that of *histolytica* cysts, and this together with one or two other points might suggest some definite relationship between the two I do not, of course, mean to say that because of this one supposed similarity the so called iodine bodies are to be regarded as *histolytica*

It is to be noted that apart from using a combination stain mixed fresh each day it is also of importance to see that too much food débris is not used to make the film preparation Where this precaution is neglected the iodine may be all absorbed by the gross matter present, leaving the cysts perfectly colourless A little practice in making just the correct type of film will obviate this

The only other objects likely to be met with besides protozoal cysts which take on this vivid greenish yellow are plant hairs and a few mould spores The former, described in a former paper, are easily recognised for what they are,[1] while the latter can be differentiated from cysts by their shape or size and by the absence of the characteristic markings of the various types of protozoal cyst The vivid colour of plant hairs suggests that the walls of these protozoal cysts are composed, like the plant hair, of cutin *Blastocystis hominis* on the other hand, always stains a cherry red or terracotta colour according to the stain combination used The large vacuole which is here contained takes on the same tint as the background while the nuclei pushed to the side stain deeply, as described in the last sentence They are of vegetable origin and possess very thin walls, and with the combination stain described in this paper it is impossible for them to be confused with true protozoal cysts, as is sometimes done by the inexperienced when the simple iodine stain is employed

What are probably dead leucocytes stain apparently varying tints of brown to greenish yellow All the other débris takes on a more or less brownish tint, while bacteria remain practically unstained, or, if they do stain the deep red background in which they are prevents them owing to their size, from becoming obtrusive and so distracting to the eye

The background, therefore in such preparations is a more or less homogeneous shade of red according to the kind of stain combination used in which the bacteria, for the reasons given above do not force themselves on the vision, while the larger particles of débris owing to their tint, do not obtrude themselves on the eye The only objects which stand out in such glaring contrast with this background are the protozoal cysts especially those of *coli* and *histolytica* plant hairs and to a less extent the iodine bodies and a few mould spores

I wish here to emphasise the need for employing the strong solution of iodine above mentioned in the stain combination Even in preparations made with iodine alone, this will be found to be a great improvement on the ordinary Gram strength iodine as nuclear and other details are much more strongly brought out

The tint of the background varies according to the stain combination used Rubin S necessarily gives the deepest red, eosin is deep with rather more yellow in it while the Stephens's scarlet writing fluid is similar to the eosin but less ntense and a more marked yellowish red To get the best colour contrast between background and cyst wall it is a matter of great importance to take into consideration the source of illumination used Much the best contrast is got by using the rubin S combination stain with daylight as the source of illumination Failing this, white artificial light, and failing this, a deep blue screen must be inserted below the diaphragm in the case of the eosin and the ink combination stains respectively, in order to cut off the yellow rays

---

[1] THE LANCET 1916 ii , 1100

With ordinary strong daylight the rubin S combination gives a rose-red tint to the background, while with either of the other combinations the background is a sort of salmon pink. From all the cysts stand out a brilliant greenish yellow, although the contrast is not so marked the yellower the background becomes The best contrast effect can, however soon be determined after a little manipulation by each individual worker for himself, who must bear in mind the points mentioned above regarding depth of film, and so on

I wish in conclusion to express my thanks to Mr R C M Lean M A B Sc of University College, Reading, for much valuable help in connexion with the above

Summary

The stain combinations here recommended are devised for the purpose of detecting protozoal cysts in general and more particularly those of *E coli* and *E histolytica* but they are not intended as a means of discriminating between *coli* and *histolytica* cysts respectively although there are some indications that this mode of staining may aid in the differentiation To get the best results attention must be paid to the various points mentioned The advantages claimed for the above technique are these —

1. One or other of the stain combinations can easily be obtained and rapidly made up
2 The detection of cysts and their identification are carried out in one and the same preparation
3 The contrast in colour is so striking that the cysts cannot be mistaken for anything else and the veriest tyro cannot fail to detect them if present The possibility of missing a carrier is reduced to a minimum
4 Without using too thick a preparation it is nevertheless possible to use slightly more fæces at one examination than by the simple iodine method The cysts can be picked out quite easily even in a thick clump of débris, and this is not always possible in a simple iodine preparation
5 Where doubt exists as to whether a particular cyst is to be classified as *coli* or *histolytica* accurate measurement—formerly considered a point of crucial importance but no longer to be relied on—is facilitated since the effect of halation is practically eliminated
6 The method above described reduces considerably the time spent on such examinations a point of some importance where many specimens have to be examined in a day A positive film even in the hands of the less experienced can be recognised at once while a negative film may be labelled so with certainty inside two minutes
7 Where the observer is hunting specially for the smaller cysts such as those of *Tetramitus mesnili* the Stephens s ink combination may be found preferable although it does not give such a definite colour contrast with the larger cysts In all cases the film made should be the thinnest possible and the source of illumination should be taken into account [1]

---

[1] Since writing the above the Director of the Wellcome Research Bureau has kindly given me a reference to a wet-stain method described by [illegible] in a paper "Sur la Dysenterie Amibienne" published at Saigon in 1913 In this paper the stain used was a single one either eosin methylene blue or iodine by itself Eosin alone as recommended in this paper is poor and not even as good as iodine alone [illegible]

ROYAL VICTORIA HOSPITAL BELFAST —At the annual meeting held on March 29th it was reported that during 1916 there had been 3457 intern and 25 413 extern patients and a daily average of 518 patients in the hospital and that over [illegible] operations had been performed Though the annual subscriptions have increased it is estimated that an additional sum of £[illegible] will be required during the current year owing to the continued rise in the cost of materials Five members of the medical staff are at present at the front A bequest of £10 000 from the estate of the late Miss [illegible] was announced

TOXIC SYMPTOMS AFTER THE USE OF BISMUTH PASTE

BY F A. HEPWORTH, F R.C S ENG,

TEMP MAJOR, R.A M.C CHIEF RESIDENT SURGEON, WHARNCLIFFE WAR HOSPITAL, SHEFFIELD

IN view of the increased use of bismuth paste and its great value in the treatment of infected wounds, I venture to publish the result of an investigation into a number of cases suspected of poisoning which have occurred in the surgical wards of the Wharncliffe War Hospital, Sheffield

Five men have been found to show symptoms suggesting plumbism and although under the care of different surgeons and in different wards they are alike in suffering from severe septic wounds and in the fact that all were treated by the application of bismuth and iodoform paste (B I P P) according to Professor Rutherford Morison s technique This paste has been in use here from September, 1916 and is still being used The method was very kindly demonstrated to me by Professor Morison in November and has been proved to be very beneficial

Up to Nov 3rd the paste was prepared from bismuth carbonate which was afterwards tested and no lead contamination discovered After Nov 3rd a new lot of bismuth subnitrate was used, as in Professor Morison s formula, this stock lasted for about four weeks, and it was among the cases treated during this period that those suspected of poisoning occurred. Unfortunately, the subnitrate was used up before the symptoms had been noticed, and the drug was therefore not analysed. Since the beginning of December, both bismuth carbonate and subnitrate have been used and both have been examined and declared lead free by Staff Sergeant F C Thompson, D Sc, R A M C The method of testing is added to this report as a separate note The drugs have all been obtained from the base medical stores at York

In this report seven cases are included all of which were treated by the Morison method, they represent all the most severely wounded and most septic cases treated with the bismuth paste at that time Many slighter cases were similarly treated but none showed poisoning Of the seven cases, five had symptoms of poisoning, and two were free

In the accompanying table, which gives details of the cases, it will be seen that four patients developed a *blue line on the gums* This was first noticed in Private Y, who complained of a sore mouth 10 to 14 days after his operation and was found to have a broad band of bluish pigmentation inside the cheeks, and on the sides of the tongue as well as an unusually thick line on the gums Other patients were then examined and three more were found with less noticeable but still distinct "blue lines"—Sergeant R, Private B and Private D

Anæmia was present in all seven cases, and disappeared as the wounds healed *Constipation* was especially noticeable in Private Y Both symptoms are so common among men with severe wounds that they are of little diagnostic value No neuritis wrist drop, colic or headache has been noticed *Mental stupor* was a troublesome feature in one patient (Private D) but had been developing before his treatment with bismuth paste

Loss of sphincter control delirium, and sleeplessness continued for two or three weeks in the case of Private J B who was extremely ill and thought to be dying His infection was severe and his knee joint was involved. Improvement followed, not directly after amputation, but as the suppurating amputation wound cleaned up His symptoms, therefore may have been due to plumbism, but are much more likely to have been caused by septic intoxication or iodoform poisoning

Blood changes were looked for by our pathologist, Major A E Naish R.A M C (T) but no granules were found in the corpuscles The *urine* was also examined for lead, but no trace found in any case

Opinion was at first strongly in favour of the view that the symptoms in these patients were due to lead absorption especially as the cases occurred while one particular batch of bismuth preparation was in use But in Sir Thomas Oliver s book on "Lead Poisoning" p 135 it is stated that—

> A blue line on the gums with difficulty distinguished from that caused by lead may be observed in persons to whom large doses of bismuth have been administered by the mouth or who, as the subjects of empyema have had injected into the fistulous track in their thoracic wall bismuth emulsion

DETAILS OF CASES, INCLUDING THOSE WITH TOXIC SYMPTOMS AFTER USE OF BISMUTH PASTE

—	Disease	Date of wound	Severity and character of wounds	Date of operation and application of B I P P	Date of symptoms	Severity and character of symptoms.
Pte Y	G.S W both legs Double amputation in France	July 7, 1916	Large granulating flap wounds at level of knees	Double re-amputation. Dec. 5 1916	Dec 16 onwards	On Dec. 16 1916, complained of sore mouth; had broad blue line on gums and cheeks Dec. 22. Constipation no colic anæmia. Wounds healed by Dec. 30.
Pte. D	G S W left thigh G.S W left foot. Comp fracts of femur and tarsal bones	Aug 6 1916.	Both wounds severe. Much suppuration. Fractured femur in bad position	Nov 17 1916	Dec 20	Blue line on gums Dec. 20th. Mental stupor on Dec. 1st, but had been difficult to manage and stuporose to less extent during early part of November Anæmic all the time Wounds healed by Jan 7th, 1917
Pte M	G.S W left shoulder Fract of greater tuberosity of humerus Joint involved	Oct. 25 1916	Wound pouring with pus Temperature 103° every evening	Nov 12, 1916.	—	No toxic symptoms Steady improvement
Pte B	G S W right thigh Comp fract. femur G.S W left wrist.	Nov 10, 1916	Septic wounds Femur comminuted	Nov 27 1916.	About Dec 20	Well marked blue line on gums Anæmic (but was so before operation)
Sgt. R	G S W right shoulder Fract. of greater tuberosity of humerus Joint infected	Nov 13, 1916	Deep wound tracking behind joint, and under scapula. Septic	Nov 27, 1916.	About Dec 20	Pyorrhœa alveolaris, with thin blue line on gums Transient anæmia.
Pte J B	(a) G S W left buttock. (b) G S.W left thigh Comp fract. femur Knee-joint infected	Nov 16 1916	Infected but well treated by Carrel method. Bone projecting into supra-patellar pouch of knee	(1) Nov 27 (2) Dec 14	Dec. 4th and later	No blue line on gums Delirium sleeplessness high temperature loss of control over sphincters All these symptoms were considered to be due to septic infection
Pte H	G.S W right thigh Comp fract of femur	Sept.15, 1916	Track through thigh from side to side. Septic Bone comminuted.	Oct 27 1916.	Nil	No toxic symptoms Progress in this case was much better after the use of the bismuth paste. He had shown practically no improvement previously

And in our cases, with the exception of the "blue line," no typical symptom of plumbism has been present, although with so intense a blue line as occurred in the patient, Private Y, other symptoms might reasonably be expected to occur In view of the importance of a correct diagnosis it is very unfortunate that none of the bismuth preparation used in treating these particular cases was obtained for chemical examination

I desire to acknowledge the help of Major Naish, Mr M H Phillips, and Dr J C Maddison in the investigation and treatment of the cases referred to

Method used for detecting a trace of lead in bismuth carbonate or subnitrate, by Staff Sergeant F C THOMPSON, D Sc, R A.M C—The usual tests for lead are useless When dissolved in nitric acid, lead can be precipitated as PbO_2 on the anode of an electrolytic cell, while bismuth goes to the kathode The following method, which is simple, very delicate, and requires no special apparatus or skill, has been worked out for the purpose

Dissolve 5 grammes of the bismuth compound in 10 c.c [of concentrated hydrochloric acid. Dilute until bismuth oxychloride is just precipitated, and re-dissolve in a few drops of HCl Filter if necessary through a *dry* funnel into a dry beaker Add 3 c c concentrated sulphuric acid, cool and add an equal bulk of alcohol, and put aside. 0·07 per cent Pb gives a milkiness in about five minutes 0·02 to 0·03 per cent Pb gives a faint milkiness in about four hours

---

THE

RELATION OF STRUCTURE TO FUNCTION AS SEEN IN A MECHANISM OF THE VENOUS SYSTEM

BY F WOOD JONES, D Sc, M B, B S LOND

PROFESSOR OF ANATOMY LONDON SCHOOL OF MEDICINE FOR WOMEN

IT is difficult to imagine that the arrangement of the venous system, to which attention is directed in this note, can have escaped the observation of anatomists and physiologists from the time of Harvey onwards When once the cardinal facts of the circulation of the blood had been demonstrated it is beyond belief that any mechanical aid towards the efficiency of the circulation should have escaped notice But recorded observations upon this particular detail have not so far been encountered in the literature, and it is to be remembered that a just conception of the mechanism of venous return came relatively late in the story of unravelling the mysteries of the circulation

That John Hunter had no note upon it, in such of his manuscripts as are lost to us is difficult to believe But had the observation ever received common currency it is unlikely it would have escaped the attention of the Rev William Paley, nor could it have failed to furnish material for a Bridgwater treatise However, this particular phase of anatomical literature does not dwell upon the detail to which attention is here directed, and this silence is shared by modern text-books on anatomy and physiology It is this fact which alone justifies publication to-day That a search of the literature has not revealed an exposition of a simple mechanical contrivance in the animal body is my excuse for publication, but I would apologise in advance to such eighteenth century philosophers as may have appreciated and recorded the conditions in works which I have, so far, overlooked

The primary tubular elements of the vascular system are primitively pulsatile, and this pulsatile power is manifested at an extraordinarily early period Not only is the first formed heart-tube capable of contraction and dilatation, but every mesoblastic muscular cell of the primary tube is endowed with an inherent power of rhythmic movement By this power, aided by a secondary valve system, the blood is urged onwards to distal parts of the body But when the blood, so urged, has come to the end of the outgoing arterial system and enters upon its meandrine pilgrimage of the tissue spaces it loses, little by little, this propulsive *vis a tergo* Yet from its tissue wanderings the blood still has to find its way along the veins upon its return journey to the heart.

It is obvious that, under normal circumstances, this journey has to be undertaken in the absence of any effective pulsatile propulsion from the heart. Many mechanical aids may come to the assistance of the returning venous stream. In the first place, since pulsation is so inherent a property of embryonic vascular channels, it might be expected that pulsatile veins should not be unknown, and as a matter of fact, their existence has long been demonstrated, and the occurrence is highly instructive In 1851 Professor T Wharton Jones[1] first noticed pulsation in the veins coursing in the membrane of a bat's wing On the average the veins contracted 10 times every minute, and these contractions aided by a system of valves, were seen under the microscope to propel the blood onwards towards the heart Such a striking phenomenon at once arrested his attention, and formed the subject of a series of communications to the Royal Society The circumstance also demanded an explanation, and Wharton Jones suggested that such an arrangement was necessary in the bat's wings, since they 'on account of their extent are, as regards their circulation, in a considerable degree, though not entirely, beyond the sphere of the heart's influence" This explanation may be partly satisfactory, but it cannot wholly account for the phenomenon Many structures as far removed from the sphere of the heart's influence could be cited, and pulsatile venous channels in these structures would be sought in vain The peculiarity of the veins of the bat's wing membrane lies in the fact that they course in an outlying part of the body which is totally unprovided with muscles capable of exerting pressure upon them In the absence of skeletal muscle masses in this very specialised manus the pressure which urges the blood onwards must be furnished by the muscle of the veins themselves, and the primitive pulsatile possibilities of vascular channels is called into being

---

[1] Discovery that the Veins of the Bat's Wing (which are furnished with Valves) are Endowed with Rhythmical Contractility and that the Onward Flow of Blood is Accelerated by Each Contraction Phil Trans. Feb 5th, 1852.

That the pressure exerted by surrounding skeletal muscular masses is the chief agent in propelling venous blood along the veins is not to be doubted, and this fact is recognised by every physiologist It is the purpose of this note to point out that in this method of producing venous return structure is related to function in a very striking manner

We may make a generalisation which amounts to the statement of a definite law of animal economy, that (1) *venous channels which run their course in the midst of muscle masses are multiple*, and that (2) *when emerging into intermuscular spaces these plexiform vessels unite to form single channels again* This might be translated into the terms of anatomical nomenclature by saying that arteries are accompanied by single veins in intermuscular spaces, but are accompanied by irregular and multiple venæ comites when passing in intramuscular planes

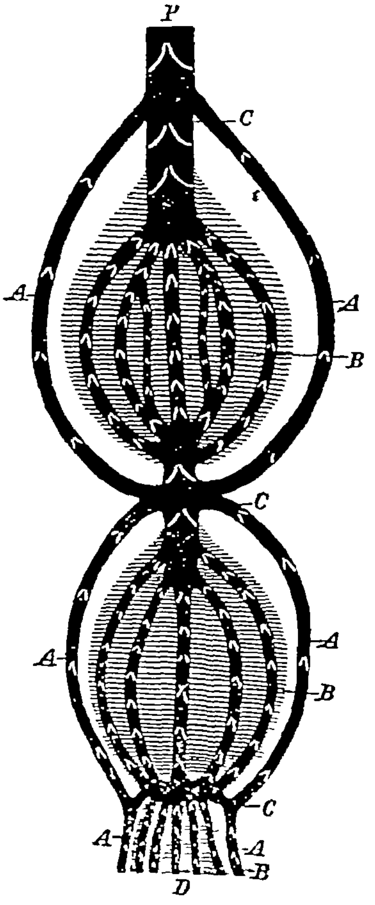
This is a very simple arrangement, but it has led to many complications in anatomical nomenclature Anatomists rather despise venæ comites, since they are irregular and variable channels, and in many cases these venæ comites are but ill described and often they are not named harmoniously with the terminology employed for the accompanying artery The anatomical purist prefers a discrete and constant channel to which to assign a definite name Instances could be multiplied to weariness, but it will be enough to point to the radial and ulnar veins which have no precise anatomical relation to the like-named arteries, which are themselves accompanied by venæ comites The radial and ulnar veins are, properly, the complex venous channels which accompany the radial and ulnar arteries in their course among the muscles of the forearm This question of nomenclature will not be proceeded with further, the purely functional meaning of the arrangement will alone be dealt with

It is obvious that if blood is to be squeezed back to the heart by the pressure of muscular masses the most efficient mechanical disposition will be achieved by a large series of venous channels containing a large amount of venous blood becoming subjected to pressure whilst lying in the midst of contracting muscle masses We may say that in the interstices of muscle groups there is a valved venous sponge which is squeezed by the muscles when they undergo contraction But muscle groups have a definite disposition and spaces exist between the groups—notably at the flexor surfaces of the joints in the limbs—and in these spaces no pressure is exerted In these spaces the meshwork of venous channels gathers itself together again and forms a single tube and this tube is invariably equipped with well developed valves The sponge is emptied by muscle pressure into this tube and the return of the blood is made impossible by the presence of the valves In a simple mechanical way the intramuscular venæ comites may be likened to the bulb of a syringe which is compressed by the muscles, the single valved channel to the valved nozzle of the syringe

Now it is to be noted that this arrangement may be several times repeated upon the course of an individual venous channel the repetition occurring as often as the conditions of subjection to muscular pressure and freedom from this pressure may recur In the limbs for instance there is an intramuscular pressure sponge or syringe bulb in each segment represented by the complex deeply seated venæ comites of the named arteries In the flexor intermuscular space over each joint is a single valved channel or syringe nozzle The blood is therefore squeezed from stage to stage by the pressure of a series of reservoirs connected up in line as one might imagine a linked series of Higginson syringes

It is at once apparent that such is a highly efficient mechanism when limbs or parts are moved in orderly and leisured fashion segment by segment But if the whole limb or part be thrown into a state of contraction or if the contraction of the several segments follow one another with great rapidity the several groups of deep intramuscular veins may be compressed simultaneously or in very rapid succession Such a state of affairs would lead to a blockage of the venous return from the part In order to meet this demand a second system of superficial veins, which are not subjected to muscle pressure, is called into play We may make a second generalisation and state that—*at all those points at which the deep intramuscular veins become freed from pressure and appear as single, valved tubes there are connecting, valveless branches between the deep and superficial veins, and at each of these points an alternative course is offered to the blood*

When the muscles of the next segment nearer the heart are relaxed the blood will return by the deep intramuscular veins, gaining an added impulse by the next contraction of the muscles, but when these muscles are contracted it can pass by the superficial veins to the next discrete channel beyond the contracted-muscle mass It is not necessary to press this matter further, since its simplicity is self evident and a diagram is added to render the details more obvious. One or two simple outcomes of this arrangement are, however, worthy of notice



Purely diagrammatic representation of the venous circulation of a limb *A* Superficial (subcutaneous) veins *B* Veins (in shaded areas) which run in the midst of muscle masses. *C* Single channels in the interspaces between the muscle masses of different segments. *D* Distal extremity *P* Proximal extremity

When the muscular system is entirely relaxed, as in sleep the heart will propel blood to its distal arterial ramifications, but the absence of muscular contractions will impede its return to the heart, venous blood will, therefore, tend to accumulate in the relaxed distal parts In this way a large proportion of the blood of the body may become lodged in the venous system. Upon waking this blood must be returned to the heart to ensure the proper arterial supply to the brain and other organs It is for this reason that muscular contractions of the limbs—the familiar stretching — accompany the waking of such animals as sleep lying down in a state of muscular relaxation Yawning, by causing a suction in the thorax and a compression of the abdomen attains the same ends The blood is squeezed home from outlying parts into the cavities of the body, and finally to the heart It is noteworthy that animals which do not lie down to sleep or do not thoroughly relax their muscles in sleep do not stretch or yawn when waking

One other effect is of peculiarly human interest If the legs are dependent but are not engaged in any special muscular activity, venous blood will tend to gravitate into the veins The deep intramuscular veins are supported by the muscles and cannot overfill and there will therefore be a tendency for the superficial veins to become distended with blood This is the etiology of varicose veins in sedentary persons On the other hand if the intramuscular veins are vigorously and continuously compressed by muscular action the burden of returning the venous blood will again be thrown upon the superficial veins This is the etiology of varicose veins in athletes

A NOTE ON THE

IMMEDIATE AFTER-TREATMENT OF THE GUILLOTINE AMPUTATION STUMP,

AND THE PREVENTION OF SECONDARY HÆMORRHAGE

By H F WOOLFENDEN, F R C S Eng
CAPTAIN R A M C (T C),
AND
J CAMPBELL, M D Liverp ,
CAPTAIN R A M C (S R)

The guillotine amputation stump usually arrives in the base hospital with a not inconsiderable amount of retraction of the skin, more especially after it has been treated for several days without any effort being made to prevent the retraction Any extension applied to the skin in order to be really effective should commence immediately after operation, be continuous, and result in a more or less complete covering in of the stump These ends seem to be most satisfactorily attained by the following method, which we have used for a long time in such cases in the hospital with which we are connected

On the completion of the amputation each of the quadrants of skin is perforated with the knife by a pair of stab incisions about 1 inch apart and 1½ inches from the edge, and a loop of sterilised tape 10 inches long is passed through each pair of perforations (as shown in the diagram) so that the tension is borne by the surface of the skin when the loop is pulled on The loops of tape are gently pulled down by the assistant and the stump is dressed and firmly bandaged After this the stump is placed in an ordinary Thomas knee or arm splint and supported in the usual fashion The loops of tape are then attached to the end of the splint by fairly stout rubber tubing tightened to the required degree and altered from time to time Any subsequent dressing can readily and easily be accomplished without slackening the extension by merely removing the dressing from between the loops of tape On the second to the fourth day the tapes are removed and the extension is kept up by strips of crinoline bandage To the edge of one end of each strip are attached a pair of ordinary metal hooks These pieces of bandage are glued to the skin by collodion with the hooks placed about 1 or 2 inches from the skin edge A loop of tape is then passed round the hooks and rubber applied as before The hooks and collodion are best changed every two or three days It is most important that the skin should never be allowed to retract when changing the soiled hooks , this can be prevented by an assistant keeping the skin drawn down The object of the elastic extension is to maintain a continuous pull on the skin as it stretches under the extension

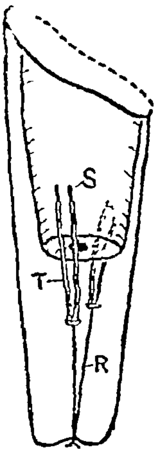


Diagram to show method of applying skin extension to the guillotine amputation stump S skin incisions T tapes R rubber tubing

By the above means every guillotine amputation can be easily transported, nearly every stump almost completely covered in when discharged to England (more especially if short flaps of ¾ inch to 1 inch have been made at the time of the operation), the stay of the patient in hospital considerably diminished, and the necessity of subsequently shortening the stump obviated, or at any rate the amount of bone requiring removal much lessened In addition the stump is considerably steadied, with consequent greater comfort to the patient

It is our invariable practice to *raise the head* of the bed so that the amputation stump looks slightly downwards By this means tracking of sepsis along the fascial planes, so frequently seen when the stump is raised becomes of quite rare occurrence The pain of subsequent dressings is largely obviated by spreading out a single layer of gauze over the raw surface of the stump and then packing the dressings on its surface or by the use of gauze soaked in glycerine

The writing of this note has been suggested during the last few weeks by the arrival in hospital of quite a large number of guillotine amputations in which no effort at all has been made to prevent skin retraction No originality is claimed, as extension in some form to the flaps has been used in France for some time , but this method has the advantage that the extension can be maintained during transit by train or boat

Secondary Hæmorrhage from the Main Artery in Amputation Stumps

During the treatment of very many amputations which have been done in casualty clearing stations and in this hospital there is one slight modification of the orthodox method that has suggested itself to us The cut artery in many instances is found to have retracted about ½ inch above the level of the cut muscles The pocket so left becomes the seat of suppuration and the source of infection, which extends some distance upwards along the outside of the artery This localised suppuration persists for some time after the rest of the stump has become healthy and is a very common cause of secondary hæmorrhage from the main artery Moreover, when such hæmorrhage occurs the difficulty of re ligaturing the artery is increased on account of its retraction

What happens is, we think, the following The fleshy part of the limb is cut through by one sweep of the knife Owing to its elasticity the artery retracts It is then seized by the forceps pulled down, the tissues round it cleared, and the artery tied and let go It retracts a little further and the opened up fascial plane becomes the seat of suppuration round the end of the artery To obviate this we have made a practice of exposing the artery about 1½ inches below the level at which we intend to divide the muscles We then divide and tie the artery and vein at this level, so that when the amputation is completed the vessels are projecting out from the stump By this means the incidence of secondary hæmorrhage from the main vessels has, we think been very much lowered, and in the few cases in which it has occurred it has been very much more easily dealt with, as the end of the artery can be readily re ligatured without the necessity of further incision

The occurrence of secondary hæmorrhage in wounds generally —Another very fertile source of secondary hæmorrhage is the leaving of a stiff rubber tube in contact with a large arterial trunk after the operation of draining a wound with the almost certain result that ulceration of the vessel occurs, followed by fatal hæmorrhage in many cases It would at first sight seem unnecessary to point this out, but we can recollect very many patients coming down from the casualty clearing stations with large rubber tubes pressing against their femoral or brachial arteries These have always been immediately removed but only too frequently the damage has already been done, and within a few days dangerous and often fatal hæmorrhage takes place from the eroded artery

Medical Societies.

MEDICAL SOCIETY OF LONDON

Traumatic and Arterio-venous Aneurysms

A MEETING of this society was held on April 2nd Lieutenant-Colonel D Arcy Power the President, being in the chair

Colonel Charters J Symonds who opened the discussion, said that whilst many cases of arterio-venous aneurysm had been submitted to operation since the war began, others had remained untreated , it would be very valuable to see both groups and so modify the views currently held His experiences had led him to correct some of his former views The most interesting form of aneurysm was that in which there was a communication between an artery and a vein either direct or by the intervention of a sac In some the communication was set up within a few hours of the trauma , in others there was considerable delay He asked for experiences as to the secondary effects of aneurysm, such as were alluded to by Sir George Makins and by Dr Bernheim of America especially cardiac and circulatory disabilities The local condition in some varix aneurysms was important , in those involving the common femoral artery and the profunda femoris there was enormous dilatation of veins, so that they looked like sinuses running through the muscles The difficulty in arresting hæmorrhage in these was very great After giving particulars of a number of these he proceeded to discuss the treatment In aneurysm of the posterior tibial artery the disability was very slight, this was also true for those at the bend of the elbow When an aneurysm existed at the base of the skull, so that the patient was kept awake at night and had nerve disturbance in consequence, it was advisable to operate Sir George Makins's view was that aneurysmal varices seldom required operation He described by means of diagrams the various operative procedures which had been devised for 'aneurysm and the degree of success which had attended them in his own experience Gangrene was a serious danger in operations on the common femoral, in the South African War it occurred in 50 per cent according to Makins In aneurysms below the middle of Hunter s canal his experience was that gangrene did not follow ligature of the vessels With regard to arterio-venous aneurysms Sir George Makins was strongly of opinion that these should be left for from two to three months to consolidate and contract and to permit the establishment of a collateral circulation But the speaker suggested that it might be wiser to operate on them early, in the same way as upon a wounded artery, thus avoiding the trouble due to adhesions which followed passive waiting Procedures which might be useful were temporary ligature of a large artery through the abdomen or compression of the common iliac artery by a band of deep fascia being sewn over it or using a portion of saphena vein sufficient to encourage early collateral circulation In aneurysm of the carotid there was danger of the supervention of hemiplegia, one or two examples of which he related He thought that much could be said in favour of operating earlier than Sir George Makins advocated. The formation of adhesions and the development of a large number of thin walled vessels, which were particularly hampering if the operation indicated was suture of the aperture in the artery, had to be taken into account

Major R H JOCELYN SWAN spoke of the need for distinguishing between arterial hæmatoma and arterio venous aneurysm By the former was meant a collection of fluid blood and clot contained under pressure in the muscular and fascial planes of the limb into which blood is forced from a laceration in the wall or complete severance of an artery or a large branch of it The clot might become softened by direct infection from the external wound, when secondary hæmorrhage might occur or, as was more common, the surface wound healed, whilst the impact of the circulating blood hollowed out a cavity in the recent clot which by organising formed a more or less thick walled laminated sac with smooth inner lining, resulting in a pulsating swelling and forming the false or traumatic aneurysm At the same time as the result of infiltration of the tissues by serum and leucocytes, a good deal of matting and fixation of the sac occurred and the anatomical lines were obscured conditions which caused difficulty when an attempt was made to remove the sac at an operation and might render the main vessel hard to find at some distance from the aneurysm An arterio venous aneurysm implied a wound both of the artery and vein, with a communication between them This might be direct—aneurysmal varix This simple form was uncommon, it was more common to find an aneurysmal sac at the distal side of the artery in addition or a sac lying between or on a side of both artery and vein with which both communicated In some cases the sac seemed to be formed mainly from the venous injury An arterio venous aneurysm might not be noticed for some weeks or months after the injury Of the recently published cases of aneurysm following gunshot injuries, of 146 which were operated upon, 106 were false aneurysms and 40 of the arterio-venous variety In his own 23 cases 16 were false and 7 arterio venous With regard to situation 40 occurred in the upper extremity and 90 in the lower 12 of the remainder being in the carotids The proportion of arterio-venous to false aneurysms was greater in the larger vessels, in the femoral it was 14 to 31 in the popliteal 8 to 21 in the posterior tibial 2 to 13, whilst in the axillary it was 3 to 9 and in the brachial 2 to 14 In the neck there were 8 arterio-venous aneurysms to 4 traumatic The physical signs of arterio-venous aneurysm differed from those of false aneurysm The bruit which might be systolic at first, became a more continuous rumble, and was conducted more widely both along vessels and bones The thrill was coarser and bubbling and often appreciated by the patient The swelling of a varicose aneurysm was usually smaller and less defined than that of a false aneurysm Dealing with treatment, he advised delaying operative procedure for some weeks unless untoward symptoms, such as gangrene, rapid increase in the size of the swelling, or increasing pain from pressure upon nerves, should force one's hands In most cases of arterial hæmatoma he advised complete rest in the hope that the whole might consolidate, whereas if a traumatic aneurysm developed it could be dealt with subsequently If an arterial hæmatoma were opened it might be very difficult to pick up the injured vessel, whereas a proximal ligature of the main trunk at the seat of election was to be avoided, for not only had the collateral circulation been given little chance of establishing itself, but also it might be seriously interfered with by the pressure of the mass of blood clot in the tissues Further, the hæmorrhage might proceed from a large branch and not from the main trunk, while ligature of the main vessel might determine the onset of gangrene in the limb When a false aneurysm was present the patient should be kept at rest with slight pressure on the swelling and the latter carefully watched for any increase in size Although operative treatment would generally be necessary, it should be deferred, if possible, until all wounds were firmly healed and collateral circulation had had a good chance of becoming established The difficulties were lessened rather than increased by waiting If the swelling had not appreciably diminished in 6 to 8 weeks, if signs of increase were present, or if pain from nerve pressure became marked, operation should be undertaken In most of his operations he had been obliged to abandon an attempt at suture and to rely upon obliteration of the vessel by ligature The operation should aim at reconstructing the lumen of the injured vessel by suture, when this was not feasible, ligature immediately above and below the injury should be carried out and the sac emptied and obliterated by suture It was neither advisable nor necessary to attempt removal of a large sac By opening the sac one made certain that no branch led into it which would keep up the aneurysm In arterio-venous aneurysm operation would seldom be required for direct fistula When the artery and vein were in communication through a sac operation was needed, owing to the gradual increase in size of the swelling He believed that ligature of both the artery and the vein, above and below the aneurysm, would be found to be the best that could be done where immediate suture was impracticable

Major W MCADAM ECCLES remarked that Colonel Symonds thought it would be well not to wait before operating on arterio venous aneurysm and ordinary traumatic aneurysm, whilst Major Jocelyn Swan thought it wise to wait He believed that both were right In the case of aneurysm in the neck he considered that the sooner one operated the better, but when the situation was one of the limbs it was right to wait for collateral circulation to be established So far he had not had a case of gangrene of the lower limbs, because he had waited for months in these cases

Captain J R. LEE of the Australian Forces, expressed his firm belief in combining the operative treatment with the administration of a vaccine to counteract the lighting up subsequently of pathogenic organisms Where it was possible, preference should be given to an autogenous vaccine He agreed as to the wisdom of waiting in cases of aneurysm of the limbs He did not agree with leaving the sac as there was evidence that it was apt to become canalised

Captain C ROWNTREE considered that aneurysmal varix with a direct arterio-venous fistula was on the whole better left alone, especially as it caused but little trouble It was a different case with the indirect variety Suture was very rarely possible though it should be aimed at It would be useful to learn the proportion of cases of successful suture One could not always be certain whether a condition was aneurysmal varix or varicose aneurysm and in some cases it was essential to incise and explore before deciding whether it should be left alone or operated upon

Dr MILLER thought, as the result of watching many cases that when an aneurysm was near nerve trunks, if the surgeon was willing to operate, he should do so at once With regard to tying the common carotid he believed that hemiplegia occurred only when embolic material found its way into the brain

Colonel SYMONDS and Major SWAN replied

A NOTE ON THE

IMMEDIATE AFTER-TREATMENT OF THE GUILLOTINE AMPUTATION STUMP,

AND THE PREVENTION OF SECONDARY HÆMORRHAGE

BY H F WOOLFENDEN, F R C S ENG ,
CAPTAIN, R A M C (T C),
AND
J CAMPBELL, M D LIVERP ,
CAPTAIN R A M C (S R)

THE guillotine amputation stump usually arrives in the base hospital with a not inconsiderable amount of retraction of the skin, more especially after it has been treated for several days without any effort being made to prevent the retraction Any extension applied to the skin in order to be really effective should commence immediately after operation, be continuous, and result in a more or less complete covering in of the stump These ends seem to be most satisfactorily attained by the following method, which we have used for a long time in such cases in the hospital with which we are connected

On the completion of the amputation each of the quadrants of skin is perforated with the knife by a pair of stab incisions about 1 inch apart and 1¼ inches from the edge, and a loop of sterilised tape 10 inches long is passed through each pair of perforations (as shown in the diagram) so that the tension is borne by the surface of the skin when the loop is pulled on The loops of tape are gently pulled down by the assistant and the stump is dressed and firmly bandaged After this the stump is placed in an ordinary Thomas knee or arm splint and supported in the usual fashion The loops of tape are then attached to the end of the splint by fairly stout rubber tubing tightened to the required degree and altered from time to time Any subsequent dressing can readily and easily be accomplished without slackening the extension by merely removing the dressing from between the loops of tape On the second to the fourth day the tapes are removed and the extension is kept up by strips of crinoline bandage To the edge of one end of each strip are attached a pair of ordinary metal hooks These pieces of bandage are glued to the skin by collodion with the hooks placed about 1 or 2 inches from the skin edge A loop of tape is then passed round the hooks and rubber applied as before The hooks and collodion are best changed every two or three days It is most important that the skin should never be allowed to retract when changing the soiled hooks, this can be prevented by an assistant keeping the skin drawn down The object of the elastic extension is to maintain a continuous pull on the skin as it stretches under the extension

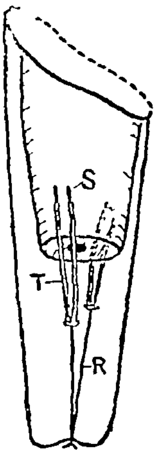

Diagram to show method of applying skin extension to the guillotine amputation stump s skin incisions T tapes; R rubber tubing

By the above means every guillotine amputation can be easily transported nearly every stump almost completely covered in when discharged to England (more especially if short flaps of ¾ inch to 1 inch have been made at the time of the operation), the stay of the patient in hospital considerably diminished, and the necessity of subsequently shortening the stump obviated, or at any rate the amount of bone requiring removal much lessened In addition the stump is considerably steadied, with consequent greater comfort to the patient.

It is our invariable practice to *raise the head* of the bed, so that the amputation stump looks slightly downwards By this means tracking of sepsis along the fascial planes, so frequently seen when the stump is raised becomes of quite rare occurrence The pain of subsequent dressings is largely obviated by spreading out a single layer of gauze over the raw surface of the stump and then packing the dressings on its surface or by the use of gauze soaked in glycerine

The writing of this note has been suggested during the last few weeks by the arrival in hospital of quite a large number of guillotine amputations in which no effort at all has been made to prevent skin retraction No originality is claimed, as extension in some form to the flaps has been used in France for some time, but this method has the advantage that the extension can be maintained during transit by train or boat

Secondary Hæmorrhage from the Main Artery in Amputation Stumps

During the treatment of very many amputations which have been done in casualty clearing stations and in this hospital there is one slight modification of the orthodox method that has suggested itself to us The cut artery in many instances is found to have retracted about ½ inch above the level of the cut muscles The pocket so left becomes the seat of suppuration and the source of infection, which extends some distance upwards along the outside of the artery This localised suppuration persists for some time after the rest of the stump has become healthy and is a very common cause of secondary hæmorrhage from the main artery Moreover, when such hæmorrhage occurs the difficulty of re ligaturing the artery is increased on account of its retraction

What happens is, we think, the following The fleshy part of the limb is cut through by one sweep of the knife Owing to its elasticity the artery retracts It is then seized by the forceps pulled down, the tissues round it cleared, and the artery tied and let go It retracts a little further and the opened up fascial plane becomes the seat of suppuration round the end of the artery To obviate this we have made a practice of exposing the artery about 1½ inches below the level at which we intend to divide the muscles We then divide and tie the artery and vein at this level, so that when the amputation is completed the vessels are projecting out from the stump By this means the incidence of secondary hæmorrhage from the main vessels has, we think been very much lowered, and in the few cases in which it has occurred it has been very much more easily dealt with as the end of the artery can be readily re-ligatured without the necessity of further incision

The occurrence of secondary hæmorrhage in wounds generally —Another very fertile source of secondary hæmorrhage is the leaving of a stiff rubber tube in contact with a large arterial trunk after the operation of draining a wound with the almost certain result that ulceration of the vessel occurs, followed by fatal hæmorrhage in many cases It would at first sight seem unnecessary to point this out, but we can recollect very many patients coming down from the casualty clearing stations with large rubber tubes pressing against their femoral or brachial arteries These have always been immediately removed but only too frequently the damage has already been done and within a few days dangerous and often fatal hæmorrhage takes place from the eroded artery

Medical Societies.

MEDICAL SOCIETY OF LONDON

Traumatic and Arterio-venous Aneurysms

A MEETING of this society was held on April 2nd Lieutenant-Colonel D ARCY POWER the President, being in the chair

Colonel CHARTERS J SYMONDS, who opened the discussion, said that whilst many cases of arterio-venous aneurysm had been submitted to operation since the war began, others had remained untreated, it would be very valuable to see both groups and so modify the views currently held His experiences had led him to correct some of his former views The most interesting form of aneurysm was that in which there was a communication between an artery and a vein either direct or by the intervention of a sac In some the communication was set up within a few hours of the trauma, in others there was considerable delay He asked for experiences as to the secondary effects of aneurysm, such as were alluded to by Sir George Makins and by Dr Bernheim of America, especially cardiac and circulatory disabilities The local condition in some varix aneurysms was important, in those involving the common femoral artery and the profunda femoris there was enormous dilatation of veins, so that they looked like sinuses running through the muscles The difficulty in arresting hæmorrhage in these was very great. After giving particulars of a number of these he proceeded to discuss the treatment In aneurysm of the posterior tibial artery the disability was very slight, this was also true for those at the bend of the elbow When an aneurysm existed at the base of the skull, so that the patient was kept awake at night and had nerve disturbance in consequence it was advisable to operate Sir George Makins's view was that aneurysmal varices seldom required operation He described by means of diagrams the various operative procedures which had been devised for aneurysm and the degree of success which had attended them in his own experience Gangrene was a *serious danger in operations* on the common femoral, in the South African War it occurred in 50 per cent according to Makins In aneurysms below the middle of Hunter s canal his experience was that gangrene did not follow ligature of the vessels With regard to arterio-venous aneurysms Sir George Makins was strongly of opinion that these should be left for from two to three months to consolidate and contract and to permit the establishment of a collateral circulation But the speaker suggested that it might be wiser to operate on them early, in the same way as upon a wounded artery, thus avoiding the trouble due to adhesions which followed passive waiting Procedures which might be useful were temporary ligature of a large artery through the abdomen or compression of the common iliac artery by a band of deep fascia being sewn over it or using a portion of saphena vein sufficient to encourage early collateral circulation In aneurysm of the carotid there was danger of the supervention of hemiplegia one or two examples of which he related He thought that much could be said in favour of operating earlier than Sir George Makins advocated. The formation of adhesions and the development of a large number of thin-walled vessels which were particularly hampering if the operation indicated was suture of the aperture in the artery had to be taken into account

Major R H JOCELYN SWAN spoke of the need for distinguishing between arterial hæmatoma and arterio-venous aneurysm. By the former was *meant* a collection of fluid blood and clot contained under pressure in the muscular and fascial planes of the limb into which blood is forced from a laceration in the wall or complete severance of an artery or a large branch of it The clot might become softened by direct infection from the external wound, when secondary hæmorrhage might occur or, as was more common, the surface wound healed, whilst the impact of the circulating blood hollowed out a cavity in the recent clot which by organising formed a more or less thick walled laminated sac with smooth inner lining, resulting in a pulsating swelling and forming the false or traumatic aneurysm At the same time, as the result of infiltration of the tissues by serum and leucocytes a good deal of matting and fixation of the sac occurred and the anatomical lines were obscured conditions which caused difficulty when an attempt was made to remove the sac at an operation and might render the main vessel hard to find at some distance from the aneurysm. An arterio-venous aneurysm implied a wound both of the artery and vein, with a communication between them This might be direct—aneurysmal varix. This simple form was uncommon, it was more common to find an aneurysmal sac at the distal side of the artery in addition or a sac lying between or on a side of both artery and vein with which both communicated In some cases the sac seemed to be formed mainly from the venous injury An arterio-venous aneurysm might not be noticed for some weeks or months after the injury Of the recently published cases of aneurysm following gunshot injuries of 146 which were operated upon 106 were false aneurysms and 40 of the arterio-venous variety In his own 23 cases 16 were false and 7 arterio-venous With regard to situation, 40 occurred in the upper extremity and 90 in the lower 12 of the remainder being in the carotids The proportion of arterio-venous to false aneurysms was greater in the larger vessels, in the femoral it was 14 to 31, in the popliteal 6 to 21 in the posterior tibial 2 to 13, whilst in the axillary it was 3 to 9 and in the brachial 2 to 14 In the neck there were 8 arterio-venous aneurysms to 4 traumatic. The physical signs of arterio-venous aneurysm differed from those of false aneurysm The bruit, which might be systolic at first became a more continuous rumble and was conducted more widely both along vessels and bones The thrill was coarser and bubbling and often appreciated by the patient. The swelling of a varicose aneurysm was usually smaller and less defined than that of a false aneurysm Dealing with treatment, he advised delaying operative procedure for some weeks unless untoward symptoms such as gangrene, rapid increase in the size of the swelling, or increasing pain from pressure upon nerves, should force one's hands In most cases of arterial hæmatoma he advised complete rest in the hope that the whole might consolidate, whereas if a traumatic aneurysm developed it could be dealt with subsequently If an arterial hæmatoma were opened it might be very difficult to pick up the injured vessel, whereas a proximal ligature of the main trunk at the seat of election was to be avoided, for not only had the collateral circulation been given little chance of establishing itself, but also it might be seriously interfered with by the pressure of the mass of blood clot in the tissues Further, the hæmorrhage might proceed from a large branch and not from the main trunk, while ligature of the main vessel might determine the onset of gangrene in the limb When a false aneurysm was present the patient should be kept at rest with slight pressure on the swelling and the latter carefully watched for any increase in size Although operative treatment would generally be necessary, it should be deferred, if possible until all wounds were firmly healed and collateral circulation had had a good chance of becoming established The difficulties were lessened rather than increased by waiting If the swelling had not appreciably diminished in 6 to 8 weeks, if signs of increase were present, or if pain from nerve pressure became marked, operation should be undertaken. In most of his operations he had been obliged to abandon an attempt at suture and to rely upon obliteration of the vessel by ligature The operation should aim at reconstructing the lumen of the injured vessel by suture, when this was not feasible ligature immediately above and below the injury should be carried out and the sac emptied and obliterated by suture. It was neither advisable nor necessary to attempt removal of a large sac. By opening the sac one made certain that no branch led into it which would keep up the aneurysm In arterio-venous aneurysm operation would seldom be required for direct fistula When the artery and vein were in communication through a sac, operation was needed, owing to the gradual increase in size of the swelling He believed that ligature of both the artery and the vein, above and below the aneurysm would be found to be the best that could be done where immediate suture was impracticable

Major W MCADAM ECCLES remarked that Colonel Symonds thought it would be well not to wait before operating on arterio-venous aneurysm and ordinary traumatic aneurysm, whilst Major Jocelyn Swan thought it wise to wait He believed that both were right In the case of aneurysm in the neck he considered that the sooner one operated the better, but when the situation was one of the limbs it was right to wait for collateral circulation to be established So far he had not had a case of gangrene of the lower limbs, because he had waited for months in these cases

Captain J R LEE, of the Australian Forces, expressed his firm belief in combining the operative treatment with the administration of a vaccine to counteract the lighting up subsequently of pathogenic organisms Where it was possible preference should be given to an autogenous vaccine He agreed as to the wisdom of waiting in cases of aneurysm of the limbs. He did not agree with leaving the sac as there was evidence that it was apt to become canalised

Captain C ROWNTREE considered that aneurysmal varix with a direct arterio-venous fistula was on the whole better left alone especially as it caused but little trouble It was a different case with the indirect variety Suture was very rarely possible, though it should be aimed at. It would be useful to learn the proportion of cases of successful suture One could not always be certain whether a condition was aneurysmal varix or varicose aneurysm and in some cases it was essential to incise and explore before deciding whether it should be left alone or operated upon.

Dr MILLER thought as the result of watching many cases that when an aneurysm was near nerve trunks if the surgeon was willing to operate he should do so at once With regard to tying the common carotid he believed that hemiplegia occurred only when embolic material found its way into the brain

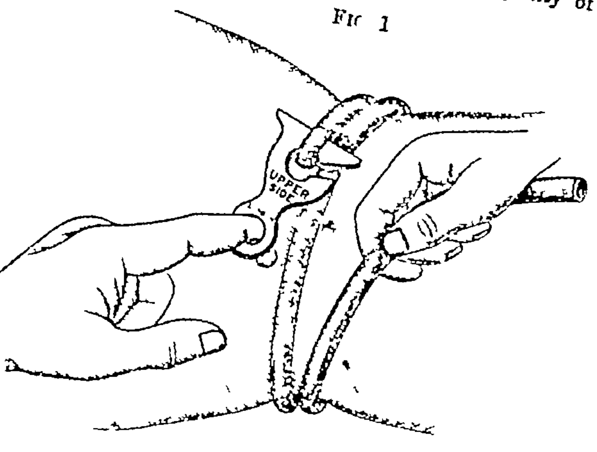
Colonel SYMONDS and Major SWAN replied.

New Inventions.

A NEW TOURNIQUET

THE question of tourniquets, both in war surgery and in operations on the extremities, has been rather prominent recently, and some correspondents to THE LANCET have advocated the use of pneumatic tourniquets It is obvious, however, that these are not suitable either for the arrest of severe hæmorrhage or the compression of a large artery such as the femoral, though they may be satisfactory for the compression of veins to facilitate the intravenous administration of drugs, such as salvarsan and its substitutes What is required in the design of a tourniquet is simplicity of application, strength, and security The fastening which is here depicted has all these merits It consists essentially of a shaped metal plate (see illustrations) with a wide base and two circular openings One of these is complete, whilst the other is split so that the rubber tubing which supplies the elastic compressing force can be slipped into it

FIG 1



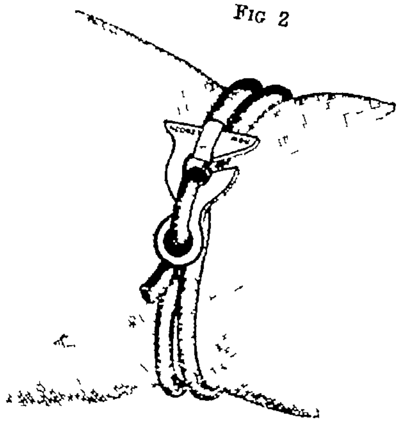
Method of application

The method of application is as follows —

The left forefinger should be hooked through the complete ring (Fig 1) and the plate held on the upper aspect of the limb, whilst the first turn of the tourniquet is passed round and under the limb and beneath the metal plate The base of this is then pressed down on the rubber so that it is held secure, while the right hand is again passed beneath the limb to apply the second turn of the tourniquet with sufficient pressure to obliterate the arterial circulation When the circular outline of the tubing becomes flattened by forcible stretching it can easily be slipped through the lateral slot in the proximal opening, the size of which is calculated to prevent the escape of the tube Any subsequent slipping of the tourniquet is then guarded against by threading the tubing through the complete ring (Fig 2) and pulling it tight. Two turns of the rubber tubing are sufficient for the lower extremity, and in the case of the arm the necessary compression can easily be obtained with a single turn It is, of course, necessary to protect the skin of the limb in the usual way with a fold of lint or other soft material

I have used this new tourniquet in a number of cases with complete satisfaction, and the necessary manœuvres to apply it take longer to describe than to carry out I have been agreeably surprised to find that an inexperienced dresser can apply it successfully when no instructions at all have been given to him

FIG 2



Applied

Three points should be especially noted —(1) The complete ring is for the forefinger of the left hand, where it should remain till the tourniquet is in position, (2) by pressing the widened base on to the first turn of the tube around the limb all loss of tension is avoided, and (3) the slot of the incomplete ring should be directed towards the right hand of the surgeon, and to ensure this one aspect of the metal plate bears the words "upper side"

I am much indebted to Messrs Down Brothers, St Thomas s street, London, S E, for the care with which they have carried out my design

A SPLINT FOR THE WRIST DROP OF RADIAL NERVE PARALYSIS

THIS splint, a description of which is supplied by Mr Bryden Glendining, F R C S, was originally extemporised by a member of the firm of Henry A Murton, Ltd, surgical instrument manufacturers, of Newcastle on Tyne, who was serving in the Army and was invalided from the front He became a patient in the Duchess of Bedford's Woburn Military Hospital, and designed the appliance to meet his own case The splint is made of aluminium, and consists of wrist portion (Fig 1), moulded and shaped to adapt itself to the volar surface of the wrist and lower ends of the radius and ulna, and attached by a webbing strap and buckle, and palmar portion (Fig 2), which is shaped and cut out for the hand, and at the same time is capable of extension whereby it can be lengthened or shortened according to the size of the hand, or according as it is desired to carry the support to the metacarpo-phalangeal joint only, or to the first inter phalangeal joint, a fly nut in the splint looking the sliding surfaces and fixing the apparatus at the required length Between the wrist and palmar sections the splint is hinged and fitted with two strong wire springs, which act in the direction of dorsal flexion, so that, unless counteracted by action on the part of the wrist and hand flexors, the position assumed is constantly that of hyperextension The support is not carried beyond the first inter phalangeal joint, since it is considered more beneficial for patients to exercise the fingers by means of the lumbrical muscles attached to the back of the extensor tendons over the first phalanges

FIG 1

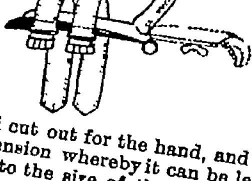

FIG 2.

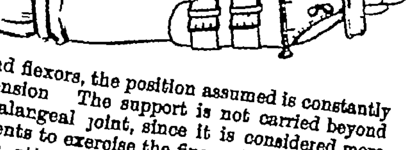

The advantages claimed for this splint are its small bulk and lightness, and the increased pleasure which patients derive from being able to use the arm and hand during convalescence It has been generally adopted at the Woburn Military Hospital

"Semprolin" Emulsion with Iron

THIS preparation admits the administration of iron *for long periods* without digestive disturbance or constipation The iron, being in colloid form, is quickly and easily assimilated With Liquid Paraffin no habit is induced as with purgatives such as cascara, aloin, &c Gives excellent results in Anæmia, &c

In 8 oz and 16-o Bottles

CONTAINING

Dialysed Iron	**20 minims**
Russian Liquid Paraffin, B P	**55%**

in each tablespoonful

Samples Free to MEDICAL MEN

William Browning & Co
MANUFACTURING & EXPORT CHEMISTS

CRYOGENINE

LUMIÈRE.

Non-Toxic. **Efficacious.** **Harmless.**

Adopted by the French Ministries for War and the Navy, also by the Poor Relief Board

Papers on "**Cryogenine**" have been read before various Medical Societies by over 90 of the most eminent Continental Medical Men In each paper clinical results of the most satisfactory character are recorded

"**Cryogenine**" is a white crystalline powder, odourless and almost tasteless, its chemical composition being **Metabenzamidosemicarbazide**

"**Cryogenine**" has a high reputation as a general **Antipyretic** and **Powerful Analgesic**

> Dr J E G——, in an article, "Action of Cryogenine on Phthisical Temperature," in "*The Lancet*," says
>
> "The above case is one out of a number of successful results obtained from the use of this remedy (Cryogenine). Contrasted with Pyramidon, which certain writers regard as the best drug for phthisical temperature, I think there can be little doubt 'Cryogenine' is the safer and more efficacious antipyretic Pyramidon shows a quicker and more pronounced fall, 3, 4 or more degrees, whereas 'Cryogenine is content with a drop of 2 or more degrees The former action is decidedly risky, as collapse may follow the sudden depression, especially if the fall be to sub-normal"

THE TREATMENT OF VENEREAL DISEASES.

Recurrent Fever
SYPHILIS

GALYL

Framboesia
Sleeping Sickness

Practical work with GALYL in the shape of

60,000 **INTRAVENOUS** (Dilute and Concentrated) and **INTRAMUSCULAR INJECTIONS** administered in Military, Naval, and the principal General Hospitals throughout the United Kingdom has demonstrated that this preparation is **more rapid and less toxic** in action than any compound of the "606" group which accounts for the **consistently excellent clinical results without any undesirable by-effects**

The other advantages of GALYL are

1.—Distilled water only necessary for making solution
2.—GALYL can be injected in the dilute or concentrated form—**intravenously**—or in oily emulsion—**intramuscularly**
3.—GALYL is a true Anti syphilitic, as shown by the results of the Wassermann test, but contains a smaller percentage of Arsenic than any of the compounds of the "606" group

Forms:

FOR INTRAVENOUS INJECTIONS:—
(1) **DILUTE.**—GALYL is supplied in neutral glass ampoules containing the necessary dose of sodium Carbonate, sterile distilled water only being used for the dissolution.

(2) **CONCENTRATED.**—A special outfit containing one dose GALYL one ampoule sterilised solution, and one small filter is supplied
DOSES:
0·10—0 15—0·20—0·25—0 30—0 35—0 40

(3) FOR INTRAMUSCULAR INJECTIONS:—
GALYL is supplied in **OILY EMULSION**
DOSES:
0 10—0 15—0·20—0 30—0·40.

The Health of the People

SOME 90 years ago the social and economic conditions in England, grievously affected by the Napoleonic wars, produced a feeling among many of the more far seeing, who were also blessed with a humanitarian sense, that the health of the people ought to be a national care. Even though that feeling took outward form mainly in designing methods whereby the ills of the poor, as far as they were the outcome of disease, should not spread to the population at large, there existed behind it a consciousness that eradication of those ills, rather than a lopping of their branches and a topping of their shoots, ought to be effected. In short, the need for making the health of the people the care of the State had become obvious to those who could read with a sympathetic heart the signs of the times, and from this position to that of to day, when by common accord we welcome the foundation of a State Department of National Health, seems but a short step—certainly one that should not have required 90 years of consideration. But to come to this conclusion is to forget that only a few people grasped the signification of the conditions in which a large proportion of the population were struggling, that the removal of those conditions was in most cases beset with the difficulties everlastingly associated with established custom and vested interests, and that the science of medicine had not acquired a familiarity with the etiology of disease that could enable its professors to preach the doctrine of prevention with sufficient authority either to arouse the public conscience or reinforce the voice of reform.

The Poor law Commissioners of 1834 perceived that ill health was a principal source of pauperism, and that the removal of the causes of ill health ought to be a more economical proceeding than the treatment of its consequences, and early public health legislation contained the germ of a National Health Department, but the nation—its units no more than its rulers—did not appreciate the splendour of the work which was beginning, resenting only the manifest drawbacks to legislation conceived, with however sensible an object, in the wrong spirit. None the less the work went on, for men were growing more liberal minded, and as medicine, leaping forward in bounds to accurate knowledge, became first an official aid and then an inspiriting counsel to further effort, sections of the community became alive to the fact that in various directions they could be relieved of masses of evil, to whose pressure they had hitherto resigned themselves. They learned that by sanitation there could be removed barriers to their health and happiness, which remained erect with no better apology than could be found in their antiquity, and, as each section was aroused, it made its claim for relief heard, with the result that the remedy best fitting the circumstances was applied. Schemes of reform initiated in this haphazard manner were entrusted for their carrying out to various departments of Government and various local authorities, with a consequent overlapping of jurisdictions and waste of energy and money, while the resulting confusion has been worse confounded by the creation of new Government bureaux and the rearrangement of local administrative machinery. The outcome has been to make the care of the health of the people, as conducted in this country, a magnificent and illogical muddle, in which fine ideas and accomplishments, many of which elicit the envy of modern civilisation, are blended with the opportunities for extravagance and dissipation of strength inevitably associated with the want of a central plan. All this has been for many years perfectly obvious to the medical profession, as well as to men and women whose public life has brought them into contact with the truths of our social existence. With them the feeling has been implicit that the health of the people, being a national asset, should have the national supervision of a State department. And now the whole nation, under the stress of war, sees eye to eye with them.

The Unionist Social Reform Committee has, therefore, put forward at a very apposite moment a well written pamphlet[1] on the subject of the health of the people, which unravels in clear terms the intricacies of the position. The writers, deliberately leaning to the economic side of their arguments for a thorough reorganisation of our care of the health of the people, demonstrate with figures the appalling loss in man power suffered by a nation which takes no heed to the health of its members. This loss they translate coldly into terms of money, mentioning sums that even in these times, while our ears learn of millions being spent daily in the conduct of the war, are so enormous as to challenge the attention of all. And, incidentally, it may be of considerable value to future progress that the popular mind should have been familiarised with the *necessity of* paying colossal sums to achieve worthy ends, poor we all shall be after the war, but we shall have learnt the lesson that great efforts are worthy of great sacrifices, and shall be ready to start a campaign against disease with the open handedness which has marked our military procedure, and, let us hope, with less grounds for the reproach of waste and disorder. A State Department of National Health is imminent, and, from the details so far made public, it seems safe to assume that in the new bureau full recognition will be accorded to the work and claims of private practice. Whatever prevention may do for the health of the people in bulk, the sick will have to be treated in detail, and it will be excellent that those practitioners who have to make good the places where the defences have broken down, or to confirm on their patients the outcome of scientific investigation, should possess the same central authority as those carrying out the work of prevention or research. In this way there will be a community of interests between the official and the private doctor from which the public will benefit.

"Soldier's Heart"

THE articles which have recently appeared in our columns, as well as the letters published in this issue, bear witness to the interest taken in the subject of "disordered action of the heart" in soldiers. The Medical Research Committee has now published a report by Dr. THOMAS LEWIS of the investigations made by himself and his colleagues at the Mount Vernon Hospital, Hampstead, which the Committee has lent to the Army Council for the purpose. No name yet suggested for the condition is quite satisfactory. A considerable number of cases returned originally as valvular disease of the heart have been included in this report, as further examination showed that they did not present convincing evidence of organic disease, and therefore came within the scope of the inquiry. As the condition is not unknown among civilians, the term "soldier's heart" is not really applicable, and as there is no proof that it is primarily cardiac any such name as "disordered action of the heart" is neither accurate nor advisable. For the impression that he is suffering from disease of the heart retards the patient's recovery. Dr. LEWIS prefers the non-committal term of "effort syndrome," though this label probably will not gain general acceptation. He considers the leading symptoms, in order of importance, to be breathlessness, præcordial pain on exertion, exhaustion, giddiness, and fainting. He notes, as of less importance, palpitation, headache, lassitude, irritability of temper, insomnia, shakiness, and flushing. A disinclination to take alcohol in any form (sometimes for conscientious reasons, but as commonly for reasons of distaste) is to be reckoned a frequent and remarkable association. The characteristic signs on examination he classifies as follows: Increased heart rate, with an exaggerated response to emotion, exercise, and posture. The response of the systolic blood pressure is similarly exaggerated, and in patients who are up and about high readings are often obtained. A diffuse apex beat and irregularity of the heart's action, increased by deep respiration, are not uncommon. Fleeting disturbances of temperature may be observed, and quickened respiration is the rule after exertion, but may also occur in the resting state. Coldness, blueness, or wetness of the palms and soles is frequent. Tremor of the hands is the rule. Deep reflexes are usually exaggerated. The urine is hyperacid and the output of calcium is increased, chiefly in the form of calcium oxalate crystals. Spermatozoa are very common in the urine. There is an increase of white corpuscles in the blood to 12,000 per c.mm. on the average, the increase being chiefly in the lymphocytes. The alteration of the blood lies in the deficiency of those salts, which, acting as buffers, ease the shock to the reaction caused by the addition of acids or alkali. In their absence the acids evolved by muscular exercise tend to irritate the respiratory centres.

In dealing with the cases at the Mount Vernon Hospital a preliminary sorting eliminated the cases of early phthisis, frank exophthalmic goitre, mitral stenosis, aortic regurgitation, and aneurysm. In Dr. LEWIS'S opinion the great majority of those patients who have merely systolic murmurs at apex or base prove not to have valvular disease. He regards auscultation as the least valuable method employed in this sorting. As to this, Dr. ALEXANDER MORISON'S protest against the modern contempt for cardiac murmurs demands consideration; if it is true that not long ago we exaggerated the significance of murmurs, that is not to say that nothing is to be learnt from their detection. A second sorting of the cases was then carried out by more detailed inquiry and by the response to graduated exercises. Where the symptoms dated from rheumatic fever or there had been recurrent rheumatism the men were not regarded as suffering from effort syndrome. Dealing with the remainder, Dr. LEWIS reports that malingering in the sense of simulation of the full symptoms of the malady is very rare, but conscious exaggeration of symptoms is almost certainly common. Of 93 patients, only 2 wished to return to active service, 41 wished for home service, and 50 for discharge from the Army. No doubt this mental attitude influences recovery. A valuable point that has been determined is the high incidence of the condition among men who were formerly in sedentary occupation. There is real necessity for more tender methods in the initial stages of training the conscript who for years has been accustomed to take no exercise. The frequency with which the symptoms develop during convalescence from febrile and intestinal affections suggests the desirability of a graduated system of re-training in such cases, while rest in bed, Dr. LEWIS holds, should be avoided at all stages of treatment, except in instances of severe præcordial pain, severe headache, or severe giddiness. It is quite obvious why the inclination of many of these soldiers to stay in bed should be discouraged; a high proportion of them are of neurotic temperament, and self-abuse is by no means unknown among them. Occupation is clearly indicated, and light employment in the open air with graduated exercises and general hygienic measures are the best therapeutic means we have. No suggestion should be made that the heart is affected. As to drugs, bromides may be of service in the initial stages, but later they are of no avail. Digitalis is without influence in these cases, and the report suggests, therefore, that its use should be discarded, the only soldiers in whom it has a real value are unfit to remain in the Army. On the lines of treatment here described it is claimed that the duration of the incapacity is considerably reduced. The average duration of stay at the hospital is now, we understand, six weeks.

As to the cause of the condition, Dr LEWIS'S conclusions are mainly negative That it is particularly apt to occur in men who have lived a sedentary life and have had some form of infection he is clear, he is satisfied that tobacco is not responsible for producing it, but is also sure that it aggravates the condition, once it has been produced Alcohol is certainly not a cause He rejects the theories of bacteræmia, toxæmia, and hyperthyroidism. On the other hand, Dr STRICKLAND GOODALL in a recent Chadwick Lecture considered the nervous and irritable heart to be due to a compensatory hyperthyroidism, initiated by excessive emotional stimulation of the supra renals, and a somewhat similar view was put forward recently by Dr LANGDON BROWN in the Hunterian Society's Oration.[1] Dr LEWIS admits that the patients show nervous symptoms, but to a less extent than those commonly classed as neurasthenics He concludes that "it is conceivable that the symptoms arise not from poisoning by toxic products but by products of faulty metabolism engendered by infectious disease The same fault of metabolism might reasonably be considered to arise from chronic infections of different types" He regards the changes in the blood and urine as strongly supporting this view We would suggest that this faulty metabolism may yet be found to be associated with one of the ductless glands, even though the thyroid may not be that one In the course of the research at the Mount Vernon Hospital Dr F R FRASER and Dr R. McN WILSON have found from their observations upon apocodeine and adrenalin that the sympathetic nervous system is more easily stimulated and also more easily depressed, but whether this is due to hypersecretion of the adrenal glands has not been determined. In this connexion the effect of acute infections in exhausting the chromaffin material in the adrenals is certainly suggestive

---

[1] THE LANCET Feb 24th, 1917 p 293

THE LATE MR. LEONARD GEORGE BOOR —There died recently at Nelson N Z, in his ninety second year, Mr L G Boor, who was educated at Christ's Hospital, London, and received his medical training at Westminster Hospital, where he was house surgeon in 1851 In the following year he took the M.R C S Eng, and practised in London till 1854, when, his health failing, he went to New Zealand, and, after a short experience of farming accepted in 1870 the appointment of surgeon to the Nelson Hospital and Asylum, which he held for 27 years Mr Boor was an enthusiastic supporter of the Volunteer movement, and was a brigade-surgeon in the New Zealand Defence Force, taking part in 1881 in the Parihaka Expedition against the Maoris, and receiving in the following year the Imperial Volunteers Decoration He was a prominent Freemason

THE CANCER HOSPITAL —At the recent annual meeting Colonel J W Webber, who presided, said that at the beginning of the war accommodation was placed at the service of the War Office and many soldiers had been treated by massage and electrical means and their return to service facilitated In the research department important investigations had been carried out During 1916 793 new cases were admitted to the wards, an increase of 20 on the preceding year, while new out-patients numbered 1519 as compared with 1424 in 1915 The total attendances of out-patients had increased from 16,154 to 23,922, and the daily average number of beds occupied was 90, or an increase of six on the preceding year The financial statement showed a deficit of £9165 on the working expenses Mr Charles Ryall, chairman of the medical committee, said he thought that no hospital had suffered more by the depletion of its honorary medical staff than the Cancer Hospital

Annotations.

"Ne quid nimis"

CHILD MORTALITY

IN a supplement to the forty-fifth annual report of the Local Government Board Sir Arthur Newsholme, medical officer of the Board, has analysed the causation of deaths occurring in England and Wales during infancy and in the next four years of life The statistics relied upon are those of the years 1911–1914, practically the four years immediately preceding the war He cites the shuddering figures of infantile mortality in some of our crowded centres, and proves by their contrasts offered in other centres, as well as in rural areas, that increased organised endeavour would save for the country a large proportion of the sacrificed babes, as well as preclude the deterioration of those who emerge alive from their first year's experience of the world In common with the report of the Unionist Social Reform Committee, he does not disguise the part played in the slaughter of the innocents by lamentable housing conditions, but without laying undue stress upon this matter alone a reticence that has its wise side, for many men and women, anxious to play their part in helping their fellows, have been driven into the inert watching of much infant suffering by the belief that it was all due to bad housing, and that bad housing could not be bettered This is a mode of thought that requires correction Even in the most backward of the towns and boroughs mentioned in Sir Arthur Newsholme's black list much saving of child life has already been secured The component factors producing excessive loss of child life vary greatly in different areas, but in every area a large proportion of the total present mortality may be obviated by enlightened administrative action. Sir Arthur Newsholme does not consider the ignorance of the working class mother to be greater than that of mothers in other classes of society, but her ignorance is more dangerous because associated with relative social helplessness How the environment of the poor child, in its widest sense, may be levelled up towards that of the well to do infant is the main and closely reasoned subject of the report With this levelling up the economic obstacles to improving the housing of the poor will disappear because the greater economy of saving lives and preventing disease will become apparent When communities appreciate that to cure disease or to palliate its sequelæ costs in the long run infinitely more than to prevent disease in children, and when the country holds, as we believe it holds already, that the preservation of the health of the child is the duty of the people, and therefore of the State, there will be little reluctance to finding the necessary money Let the good that has followed in a few localities upon thorough attempts to deal with the housing question, in places like Port Sunlight and Bourneville, be seen by the citizens of other localities in its real proportion, and the victory of reform will be won. All that is necessary is that the community should know on which side true economy lies, and one of the most useful functions of this report is the dissemination of accurate information, free of party spirit and authoritative in tone

THE NATURE AND FUNCTION OF EOSINOPHILE CELLS

THE study of eosinophilia has always been of interest to hæmatologists, and excess of it in the blood is met with in many and various morbid conditions, and gives rise to as many interpretations The origin of eosinophile cells is equally disputable, do they represent an entity special to themselves, or are they ordinary neutrophiles which in certain contingencies, and for reasons connected with biological and pathological factors, are able to assume the character of eosinophiles? Some light is thrown on such questions by Professor R Marchesini, of the University of Rome (*Il Policlinico*, Medical Section, Jan 1st, 1917), who has made a study of the presence of eosinophiles in the blood and in pathological tissues, besides carrying out experiments in animals He found that the simple fact of repeated bleedings for a long period was sufficient to produce in the bone marrow a large excess of eosinophiles, while, on the other hand, substances introduced under the skin caused evident phagocytosis but absence of eosinophilia Thus he considers the question of the origin of eosinophile cells from the bone marrow, as true individualised cells required for special functions, to be definitely solved and, as a consequence, that the eosinophile granules themselves are a product elaborated from the cell or its nucleus destined for functions of special nutrition or repair The multiplicity of pathological instances in which eosinophilia is met with is evidence that it is not bound up with any given pathological process, but rather that it constitutes a special and unique reaction of the organism both in cause and effect Eosinophilia is always present in tuberculosis, this being a disease which causes lesions in the tissues, but it sometimes seems to disappear from the circulation whenever owing to the onset of destruction of the tissues, and hence rupture and greater permeability of the vessels, the accumulation of the eosinophiles at the damaged site is facilitated Moreover, in the most severe forms of tuberculosis their production becomes exhausted owing to the toxic and cachectic state of the whole organism and with it of the bone marrow In benign cases of tuberculosis, where the foci remain shut off through necrosis of the vessels leading to the tubercle, the localisation of eosinophiles is rendered difficult, but if the stimulus continues, the cells requisitioned from the bone marrow remain in the circulation in readiness to penetrate wherever it is possible Hence their noticeable presence in the circulation has a favourable prognostic import In asthma the eosinophilia is explained by the condition of semi asphyxia and consequent change in the broncho pulmonary epithelium produced by the accumulation of carbonic acid, a powerful hæmatic poison, all these factors uniting in causing a profound alteration in hæmatopoiesis and a requisition *in situ* of numerous eosinophile cells In parasitic infection the greater or less amount of eosinophiles bears no relation to the nature of the parasite, but is associated only with the lesion caused by it and the tendency in the organism towards its encapsulation. In the granulomata, malignant tumours, and intoxications by hæmatic poisons there is a tendency in the organism towards the protection and repair of the injured tissues and organs and stimulation of the bone marrow to reproduction by the presence of the foreign bodies, which have to be got rid of or encapsuled Professor Marchesini has observed in examining sections of liver infected with actinomycosis and echinococcus that the eosinophiles which are met with in large numbers are arranged in such a manner as to prove that they contribute entirely to the formation of fibrous tissue by means of their granular secretion. In tuberculous infection of the lungs, also, the eosinophiles are most numerous where necrosed tissue has been repaired by young connective tissue As a result of his researches Professor Marchesini believes he has found the clue to the special function of eosinophiles in the organism—namely, that they must be regarded not as simple phagocytic cells, but as nutritive and plasmic cells of a high grade, having a special secretive power for defence, and for preparing a substratum for the rebuilding of substitution tissue wherever there are toxic substances to be neutralised, extraneous matter to be enveloped, animal parasites to be encapsuled, or destruction of tissue to be repaired.

SPRUE

THE war has not resulted in many instances of this tropical disease being seen in this country, but its general prevalence in the East and its occurrence in certain parts of Australia suggest that we must be on the look out for cases of this nature Therefore, we think it will be useful to refer to an excellent summary of what is known of sprue, which is given by Dr A Breinl and Dr H Priestley in the *Medical Journal of Australia* for February Sprue is a chronic inflammation of the alimentary tract, affecting chiefly the tongue, œsophagus, and small intestine This leads to degenerative changes, ulceration, and to atrophy of the liver Characteristic clinical features are the passage of numerous large, frothy, clay coloured stools, the general intractability of the diarrhœa, the intermittent course, and the progressive wasting The cause of sprue is unknown It was thought that because, from the tongue and fæces of most of the cases, certain yeast like organisms could be isolated that these were the causal agents Castellani isolated quite a number of strains, and hints that they are the responsible organisms, as do also Bahr and Ashford, but it has been shown that similar yeasts can be obtained from patients suffering from diseases other than sprue Animal experiments have been negative Morbid examination shows hyperæmia of the œsophagus and small intestine as well as ulceration, especially in the lower segments of the small gut Similar ulceration may be present in the large intestine The liver is invariably reduced in size The pancreas is sometimes atrophic and fibrous, at other times it is normal The onset of sprue is insidious, and the early stages may last for weeks or months Generally the first definite symptom is soreness of the tongue A few small rounded vesicles of whitish colour appear on the edge and tip of the tongue, later these break down, forming shallow ulcers with ragged edges, which persist for a varying period At the same time there is a patchy desquamation of the epithelium which may spread over the dorsal surface, leaving an angry looking, smooth, shiny surface In the later stages the tongue presents a complete denudation of its epithelial layer and shows longitudinal and transverse fissures which bleed easily Gastro-intestinal symptoms dominate the earlier stages Obstinate indigestion, distension and flatulence, and belching of gas occur during the whole course of the disease Diarrhœa is present to a greater or less extent throughout The stools vary in character, but often present their characteristic appearance Sallowness and definite pigmentation come on, the skin shows atrophic changes and becomes dry and shiny The general aspect of the patient alters and he becomes listless, depressed, and anxious The temperature, blood, and urine show no changes Sprue needs to be diagnosed from pellagra and from pancreatic disease From the latter, diagnosis may be extremely difficult, especially as there is some probability that the pancreas is actually implicated in sprue, from pellagra the differences in the skin changes offer the most certain distinguishing features Sprue may be fatal, if contracted late in life it nearly always is so, but early cases with suitable care, and especially by removal from the endemic area, may be cured Treatment by drugs is disappointing, emetine and collosol argentum have been tried Dietetic treatment is required In the early stages a rigid milk diet is the best, and an ampler diet must be governed solely by the general condition and bowel activity of the patient

HOSPITAL TREATMENT FOR POOR-LAW PATIENTS IN IRELAND

A CURIOUS anomaly exists in the law governing the powers of Poor law guardians in Ireland to provide special hospital treatment for Poor law patients The guardians have only power to send to the hospitals for special treatment such patients as are already inmates of the workhouse They have no power to provide any special hospital treatment for the poor patients under the care of dispensary medical officers It has long been the custom for dispensary medical officers, who considered patients to be in need of special hospital treatment, to have them formally admitted to the workhouse hospital, and forthwith despatched to a city hospital for the required treatment It is clear that in many cases no other procedure would have provided the required treatment in time to be of service Up to recently, the guardians and the Local Government Board recognised this fact, and no obstacle was put in the way of Poor law medical officers obtaining for their patients whatever treatment they thought right A few weeks ago, however, the guardians of the Listowel union, co Kerry, found themselves surcharged by the Local Government Board auditor for the expenses incurred in obtaining special hospital treatment for a patient who had only spent one night in the workhouse, and had not been an inmate at the moment the guardians made an order authorising the treatment If this ruling of the auditor is to be taken as laying down a precedent, it may interfere seriously with the efficient treatment of the sick poor in Ireland

THE ETIOLOGY OF HÆMORRHAGIC RETINITIS

A THESIS by M Amsler based on 164 cases of hæmorrhagic retinitis occurring in Lausanne (*Correspond bl f Schw Aerzte*, 1917, p 318) gives an interesting analysis of the etiology of this complaint The cases were taken from both private and hospital practice Stated in percentages, the etiological factors were as follows Arterio sclerosis, 55, heart disease, 8, albuminuria, 8, glycosuria, 3, menopause, 6 The percentage incidence in successive decades from 20 to 70 years was 4, 7, 13 27, and 36 respectively, and 13 above 70 years Nearly two thirds of the cases were in women, and in them the prognosis was relatively more favourable, especially in the cases associated with the menopause In 20 cases the typical picture of thrombosis of the central retinal vein was present, and in one of these—a woman aged 47 years—sight was restored in six months, and vision was still 4/5 four years later The low percentage of cases of albuminuria in these statistics is somewhat remarkable, but tends to support the views recently expressed by Dr P C Bardsley[1] that the prognosis in cases which show moderate vascular disease of the retina is not so bad as has generally been thought As has been shown by Mr Foster Moore,[2] cases of retinal vascular disease must be classified in various categories, the prognosis varying according to the particular type It is therefore somewhat misleading to regard hæmorrhagic retinitis as a single clinical entity, it is a symptomatic condition which must be evaluated according to concomitant factors

SUCCESSFUL OPERATION FOR A BULLET LODGED IN THE WALL OF THE LEFT VENTRICLE

WE remarked last week that the surgery of the present war had furnished instances of the successful extraction of bullets from the heart substance, while removal from the heart cavity has been reported At a meeting of the Académie de Medecine de Paris on March 3rd Professor Gaudier, of Lille, described an interesting case in which a bullet lodged in the wall of the left ventricle and had little disturbing influence on the heart's action The patient was a Russian sergeant, aged 23 years, who was wounded near Monastir on Oct 1st, 1916 While lying prone on the ground a bullet grazed the left parietal bone and passed through the supra clavicular fossa He became unconscious for a time which he could not fix, and was then able to get up Finding himself alone, he walked until he met some soldiers He was in a feeble state and walked with difficulty He could not stand upright and advanced stooping forwards He felt a severe pain at the apex of the heart, especially when he tried to straighten himself. While being carried to a dressing station he again became unconscious and passed the night in that condition He was taken by motor ambulance and train to Salonica During the journey he regained consciousness, but suffered severely from pain in the region of the heart and could not lie on either side he rested either on his back or on his abdomen He was admitted to hospital, where the wound suppurated a little He became very weak and the cardiac pain was continuous and was increased by deep inspiration He was sent to France, where he arrived on Oct 27th with the parietal wound still suppurating but the supra clavicular one healed. The pain still continued About Oct 15th he was able to get up and go about a little His general condition was good While resting the respiration was normal and the pulse 80 After going upstairs there was slight dyspnœa and the pulse varied from 85 to 90, there was no intermission Auscultation showed nothing abnormal He was put on ordinary diet and allowed to get about, but as the pain still persisted and there was some dyspnœa after rapid walking he was submitted to radioscopy, which showed that the bullet lay transversely near the apex of the heart and followed all the movements of the left ventricle It was independent of movements of the diaphragm Under ether the third and fourth left costal cartilages were exposed and divided, the pleura incised, and the "costal shutter" turned outwards by an assistant The pericardium was incised vertically for a distance of 5 cm The heart was seized in the left hand and brought outside the pericardium In the anterior wall of the left ventricle was a transverse ridge 1¼ cm long above the apex This was due to the embedded bullet, which was removed The pericardial incision was closed with catgut and the cartilages sutured During the operation there was an occasional intermission of the pulse Recovery was complicated by cough and some fever and some scattered pulmonary râles were heard The projectile was a leaden Bulgarian bullet, 42 by 7 by 5 mm, with a sheath of "maillechort," flattened at its centre Similar cases are rare, but one almost identical has been recorded by Duvergen, of Bordeaux

THE SPECIAL SCHOOL CODE

THE alterations in the regulations of the Board of Education for special schools for blind, deaf, defective, and epileptic children (Special School Regulations, 1917, Cd 8505, price 3*d* net, pp 53) represent for the most part the changes necessary to bring the regulations more into accord with the best existing practice in special schools and also in ordinary public elementary schools Since 1909, when the last regulations were issued, more extensive provision has been made for open air education and playground accommodation, the new regulations ensure that special schools shall not fall short of the standard set by the present day public elementary school Again, the facilities afforded for the detection of mental and physical defects by the institution of the School Medical Service have resulted in an increase by 50 per cent of the number of children in attendance at special schools New types of schools have been provided, not only are partially blind and partially deaf children receiving appropriate instruction, but tuberculous and delicate children are afforded opportunities of attending open air schools, where not only is the instruction more suited to their particular needs but their return to health is facilitated In view of the duty placed on local education authorities by the Defective and Epileptic Children Act, 1914, of providing classes or schools for feeble minded children, a statement of the present requirements of the Board in respect to the arrangements of special schools for mentally defective children is opportune Among other important features is the provision that blind and deaf children should be examined from time to time by a medical practitioner possessing special ophthalmic or aural experience, in the case of schools provided by local education authorities the Board requires that the medical inspection and examination of the children should be conducted by the school medical officer of the authority or under his immediate supervision. In the case of blind children the Board points out that where suitably qualified blind teachers are on the staff of the school their services would be especially useful in giving touch developing lessons to all the classes as well as lessons in Braille reading and writing A further note of progress is sounded by the inclusion of regulations for trade schools for special school ex scholars The new regulations indicate that the interests of defective children are not being overlooked during the waging of a world wide war

MALARIA IN TRINIDAD

A REPORT on malaria in Trinidad has been recently issued[1] by Dr C F Lassalle, formerly acting assistant medical officer of health for the colony, but now, we understand, promoted to a higher and more responsible office in the Public Health Service of the island. This report is in three parts, relating to (1) a spleen census made in 1914, (2) an anopheles survey carried out in 1914–15, and (3) a description of the mosquitoes found in Trinidad during an inquiry made in 1915

The spleen census—The spleen census of 1914 is the second that has been carried out in Trinidad, the first having been made in the previous year, when out of 17,495 children examined 3134, or 17 91 per cent, had enlarged spleens In the second spleen census now reported upon by Dr Lassalle 25,927 children came under examination and 3658, or 14 1 per cent, showed splenic enlargement, in addition, 1576, or 6 per cent, of those examined were suffering from anæmia. The results of the Trinidad spleen census are compared with similar examinations carried out in other countries In Mauritius, for example, in 1907–8, out of 31,022 children, 10,595, or 34 1 per cent, showed enlarged spleens, and in Ceylon, in 1908, out of 92,258 children submitted to the test, 31,421, or 34 per cent, had splenic enlargement Compared with these other two island colonies the effects of malaria in Trinidad, as tested by the presence of enlarged spleen among the children, are not specially severe, and Dr Lassalle predicts that, with enforcement of the appropriate preventive measures now in vogue, the colony will in the future show even smaller effects of malaria than at the present time A number of statistical tables relating to the various areas in the island are appended to the report

The anopheles survey—Anopheles surveys of the districts comprised within the colony were begun on March 15th, 1914, and continued up to April 30th, 1915, when they had to be temporarily suspended In all of the districts surveyed large and extensive mosquito breeding grounds were found, as well as others of smaller extent The work was carried out by sanitary inspectors who had been specially trained in the details of a mosquito survey That it is possible to rid a town of anopheles has been completely proved in Trinidad The city of Port of Spain, formerly infested by these insects, may be regarded as free, it being now a very rare occurrence to find an anopheles mosquito Through the constant efforts of the sanitary department of the town even the formerly ubiquitous stegomyia and culex have almost disappeared Dr Lassalle remarks that it may be an impossibility—mainly on account of financial considerations—to eradicate every single mosquito breeding place throughout the colony, but "it is entirely within the range of practical politics" to carry out a scheme of destruction of anopheles breeding grounds within, and for a certain distance around, all towns and villages, plantations, and other centres of population It is obvious that the reduction of the danger of malaria in a locality must be directly proportional to the reduction of the number of breeding places—the intensity of malaria infestation bearing a direct ratio to the number of mosquitoes regularly hatched out Dr Lassalle therefore recommends as a first step in a new campaign against malaria in Trinidad that anti mosquito regulations applicable throughout the entire colony should be introduced at once

---

[1] Trinidad Malaria Report By C F Lassalle, Acting Assistant Medical Officer of Health The Government Printing *Office, Port of* Spain. 1916 Pp 126

The mosquitoes of Trinidad—In his report on the mosquitoes of the colony, Dr Lassalle says that the collection of eggs, larvæ, adults, &c, obtained in the course of the above mentioned anopheles survey provided material for the study of the varieties of Trinidad mosquitoes in a more comprehensive manner than would otherwise have been possible Specimens were sent to the British Museum, the Imperial Bureau of Entomology, and to the Bureau of Entomology, Washington, for the identification of certain species A complete list is given of all the Trinidad mosquitoes now known, and a description is also furnished of the most important and best known species Dr Lassalle discusses the association of anopheles larvæ and fish in natural breeding places There seems to be some difference of opinion regarding the value of larvivorous fish in keeping down the breeding of anopheles under natural conditions In concluding his report Dr Lassalle expresses the opinion that further investigations will doubtless unearth other species of mosquito

CERTIFYING SURGEONS AND COMPENSATION FOR LOSS OF INCOME

CORRESPONDENCE has recently passed between the Association of Certifying Surgeons and the Home Secretary on the possibility of compensation being granted to those surgeons who have lost income in consequence of the abolition of investigations into accidents A loss of £12,000 per annum has been incurred by the medical profession as the outcome of the economical decision of the Home Office to dispense with these investigations, and most of this loss falls upon surgeons who hold important appointments in manufacturing districts, quite a number of them suffering to the extent of between £200 and £300 a year It was pointed out by the association that surgeons holding the better appointments had given up other work by arrangement with the Home Office, and that many had combined the duties with those of other public appointments, such as medical officer of health, when the loss could not be made good by taking fresh work The association represented also that when public officials holding appointments on similar terms are dispossessed compensation invariably follows The Home Secretary, we learn, does not see his way to grant compensation, considering that the terms of employment preclude it, and that the increase of remuneration under certain new duties should be compensatory But the association has pointed out that the new duties of their members had been of very little monetary advantage to them outside the Pottery districts, the most remunerative work of the kind instanced (that of appointed surgeon under special rules) being open to the whole profession.

Mr John H Morgan, C V O, has gone to France in the service of the Croix Rouge Français, and is taking command of a large hospital at Nevers

IRELAND

(FROM OUR OWN CORRESPONDENTS)

The Health of Belfast

AT a meeting of the city council of Belfast, held last week, it was reported that from Feb 8th to March 17th 96 cases of infectious disease had been notified—viz, 10 cases of typhus, 36 of typhoid, 25 of scarlet fever, 12 of diphtheria, and 13 of erysipelas During the four weeks ended March 17th last there were actually 12 more deaths than births (751 to 739), 52 of the deaths being due to zymotic disease 112 deaths were due to pulmonary tuberculosis 136 to respiratory diseases (exclusive of pneumonia), and 108 to pneumonia The annual average death rate from all causes was very high—24 9—while in the corresponding period of 1916 it was 20 2 The unwelcome reappearance of typhus (20 cases in all), the prevalence of typhoid (upwards of 90 cases at present in the Fever Hospital), and the rise in the general death rate are all disquieting features of the present health of the city

The Belfast Ophthalmic Hospital

At the annual meeting of the Belfast Ophthalmic Hospital held on April 6th it was reported that during the year 1916 there had been treated 4206 cases of eye disease and 1704 cases of diseases of the ear and throat, 129 urgent cases were admitted to the wards for morning dressings and 204 patients attended, making a total of 6243 passing through the hospital During the past two years, owing to five of the surgeons to the hospital being engaged elsewhere in war work, the out-patient department had only been opened on two days a week, yet the number of patients had increased, and Dr J W Browne, the senior member of the staff, single handed, has carried on all the work Financially there was a balance of £28

Hilden Convalescent Hospital, Belfast

Through the generosity of a well known member of an old Belfast family—Mrs Harold Barbour—(who gave £2000 for the equipment of the institution, and has, in addition, undertaken to subscribe £1000 per annum for its maintenance during its existence) another hospital has been founded in Belfast and district for the reception and treatment of wounded soldiers It is called the Hilden Convalescent Hospital, having been named after the great thread works with which the Barbour family is associated and is situated in one of the healthiest districts of Belfast, Galwally Park It has been established by the Ulster Joint Committee of the British Red Cross Society and the Order of St John, and is the first hospital opened by these organisations in Ulster A grant of £3000—part proceeds of "Our Day" collection—has been received from the Red Cross The institution itself, which will be shortly opened, contains 51 beds for patients and an extensive wooden building, in course of erection, as a wing to the main hospital, will accommodate an additional 75 beds. The medical staff so far appointed is as follows, all the officers being honorary —Medical superintendent, Dr John Macintosh, visiting surgeon, Dr James Taylor, visiting physician Dr J R Davison, consulting physicians, Sir John Byers, Dr R W Leslie, Dr H L M Kisack, Dr W L Storey, and Dr W Calwell, consulting surgeons Dr Robert Campbell, Dr Howard Stevenson, and Dr S T Irwin, anæsthetist, Dr W C L Fielden, radiographer, Dr S Allworthy, surgeon-dentist, Mr S A. Deans, L D S

Maternity and Child Welfare

At the annual meeting of the Belfast Health Society, held in the city hall, Belfast, the Lord Mayor presiding, the total attendance of mothers and infants at the various "babies' clubs" was reported to have nearly reached 8000, while 8145 pints of milk had been distributed, the mothers paying half the cost. An address on child welfare was given by Sir John Byers, who suggested that Belfast should take part in the proposed National Baby Week, to be held from July 1st to 7th

April 10th

CENTENARIAN —Mrs Elizabeth Elvy has died at Eastling, Faversham, in her 101st year

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS

IN *Berkshire* the number of elementary school children under the county education authority was 22,500 in 1915 The number of children examined as entrants, intermediates, and leavers was 2596 The acting school medical officer, Dr W Sisam, states that from May onwards the routine medical inspections had to be suspended, owing to depletion of the medical staff

Nutrition was found to be satisfactory in 87 per cent and in only 0 65 per cent. was it actually bad Cleanliness was satisfactory in 99 per cent. In no child were pediculi found on the body and only in six cases were they found in the head The eyesight was normal in 85 per cent of the children tested, and in only 5 5 per cent was it 6/18 or less Organic heart disease was found in 19 children (0·73 per cent) in 10 children (0 38 per cent) pulmonary tuberculosis was diagnosed and in 79 (3 04 per cent) it was suspected Non pulmonary tuberculosis (glandular articular &c) was found in 10 other children (0·38 per cent) The only treatment undertaken by the Education Committee was that for ringworm by means of X rays which was carried out at Reading Newbury and Oxford in 47 cases with satisfactory results

An education area entirely rural in character and occupation is that dealt with in Dr Frank Robinson's report on schools in *Cambridgeshire* during 1915 the borough of Cambridge not being included The number of children on the register was 12,406, of whom 3637 were examined according to the routine inspection of age groups

Nutrition was satisfactory in 83 7 and "very bad" in 1 3 per cent. In only two children were pediculi found on the body (0·05 per cent.) and in 13 cases (0 35 per cent.) in the head The vision was normal in each eye in 85 per cent. of the children tested In 6 children (0·16 per cent) organic heart disease was diagnosed Only in 1 child was pulmonary tuberculosis definitely found to be present but in 19 it was suspected (0·52 per cent) In 11 others non pulmonary forms of the disease were found Ringworm shows a most satisfactory decline compared with former years only 6 cases having been met with in routine inspection In one school there were 5 cases in one family (specially inspected) the father persistently refusing treatment "in spite of 'repeated visits by the medical staff during the year'" until prosecution was threatened This demonstrates the necessity for prompt action in dealing with culpable ignorance or obstinacy of this kind The percentage of unvaccinated children which in 1909 was 6 3 has now risen to 19 1 and in the youngest children newly admitted to school is as high as 43 5 compared with 6 7 per cent in 1909 The examination of visual defects has been carried out satisfactorily in the outlying districts by Dr Jessie Gellatly a portable electrical ophthalmoscopic apparatus with trial lenses test-types &c. adapted for bicycle transport having been employed at a total cost of £8 15s retinoscopy is done in the school cloak rooms the windows being brown papered Infectious disease was exceptionally heavy in 1915 measles necessitating 87 school closures Swabbing for diphtheria was extensively practised with good results positive evidence of infection was obtained in 31 cases

In presenting his report on schools in *Cheshire* Dr Meredith Young, the chief school medical officer, alludes to the strain on the administration during the year owing to war conditions The children examined in the entrant, intermediate, and leaver groups during 1915 numbered 17,890

Nutrition was below normal in only 7 per cent., and in no case was it actually bad Cleanliness of the body was also satisfactory in all but 2 per cent and pediculi were only found in 0·3 per cent. In 0·6 per cent they were present in the head Normal vision in each eye was found in 71 4 per cent. Organic heart disease was diagnosed in 48 children (0 27 per cent) pulmonary tuberculosis was detected in 17 children (0 09 per cent) and suspected in 42 others (0 23 per cent.) tuberculosis other than pulmonary was met with only in 34 children (0 19 per cent) Attention is drawn by Dr Margaret Ormiston assistant medical officer for South Cheshire to a senseless but very common practice in the clothing of children—viz. the excessive number of garments covering the chest and trunk as many as 11 layers being sometimes met with while very short frocks and bare knees may lead to chill of the extremities and growing pains. Children suffering from ringworm of the head are allowed in school if provided with a properly fitted cap until cured This procedure was found to be quite satisfactory Thyroid enlargement is reported as being prevalent in the rural districts of Nantwich union and in the Middlewich area several members of a family being affected in many instances and transmission being mostly through the maternal relations This would be an interesting subject for investigation as goitre or "Derbyshire neck" has not been hitherto noted in this part of the country

Owing to depletion of the medical staff on account of the war the work of school medical inspection in the county of *Durham* was limited, during the latter half of 1915, to the examination of ailing and defective children and to re inspection of children previously found to need treatment Previous to this 16 126 entrants and leavers had been examined by Dr T Eustace Hill and his assistants

Nutrition was on the whole satisfactory being considered bad in only 0 8 per cent ; in an additional 10 5 per cent it was below normal Cleanliness was also satisfactory body vermin being found in only 0 3 per cent and pediculi capitis in 1 1 per cent. Organic heart disease was detected in 91 children (0 8 per cent.); 57 of these were girls (0·72 per cent) and 34 boys (0 4 per cent) showing a marked discrepancy in the sex incidence Pulmonary tuberculosis was found in only 9 children (0 05 per cent) but was suspected in 36 other cases (0·2 per cent) non pulmonary forms were diagnosed in 0·3 per cent Energetic measures were taken in regard to the presence of vermin under Section 12 of the Children Act and in some bad cases of neglect the parents were sent to prison Unfortunately no treatment is undertaken by the county Education Committee except for defective vision and owing to the absence of the school oculist on active service comparatively few cases received attention

Dr J Middleton Martin's report on *Gloucestershire* schools deals with the routine inspection of 10,579 children, as well as with 3598 special examinations

Of the former category comprising the entrants, leavers, and intermediates the nutrition was below normal in 16 86 per cent but in only 0·09 per cent was it actually bad Body cleanliness was satisfactory in 94 5 per cent , body vermin were found in only a single instance on the head they were found in 15 children (0 14 per cent.) all being girls except two Great improvement has taken place in regard to this condition the number infected being only about half what was found when examination by the nurse was instituted first in 1908 and a badly infected head being now rarely discovered In the Tetbury urban district the percentage of infection has been reduced from 39 in 1909 to 7 in 1915 Vision in the right eye was perfect in 86 per cent and in the left eye in 85 per cent.; the proportion of children having normal vision in each eye is not stated Organic heart disease was diagnosed in 298 children (2·82 per cent.) 134 of these were among the entrant infants giving a percentage of 2·91 which seems to be remarkably high Pulmonary tuberculosis was only found in 3 cases (0·03 per cent) and suspected in 15 others in 11 children non pulmonary forms were found Treatment for teeth is carried out by the county authority as well as, in certain districts by voluntary agencies supported by local effort. Infectious diseases were especially prevalent in 1915 and 206 departments had to be closed on this account—nearly double the previous maximum of 118 in 1913 There were however fewer cases of infectious skin disease (ringworm, impetigo and scabies) than in any previous year

In *Kent* the number of children on the roll of schools under the county education authority was 84,707 and the number examined during 1915 in the code groups was 20,509

Of these children 94 per cent were well nourished and only 0 1 per cent were in a bad condition in this respect 92·2 per cent were clean as regards the body Defective vision was much more prevalent among girls (13 2 per cent.) than among boys (9·6 per cent) Heart affection (organic or functional not distinguished) was diagnosed in 2 1 per cent being somewhat more frequent in girls (2 4 per cent.) than in boy (1 9 per cent.) Tuberculosis of the lungs was found in 0·6 and suspecte in an additional 0 3 per cent and other forms of the disease in 0 1 pe cent. As to the age incidence of the specific fevers in children an interesting table shows that 50 per cent. of the boys aged 5 had already had measles At the age of 9 the percentage was 76 3 at 13 it was 83 9 The analogous percentages for whooping-cough were 34·6 51 and 51 and for scarlet fever 2·8 6 4 and 11·2 respectively For diphtheria the ratios were 1 5 3 6 and 6·2 per cent. The ratios for girls were for each disease very similar to those of the boys A table of heights and weights of 2003 boys and 2000 girls shows that in height boys and girls (in Kent) are almost equal at 9 years of age (49 7 and 49·8 inches) and at 13 years (55 6 and 55·8 inches) In weight the girls outgrow the boys in these four years; at 9 years the boys average 56 1 lb and the girls 54 6 lb at 13 years the boys have increased to 75 7 lb but the girls have gone up to 77 4 lb The relative increase is however, not so marked as in children in London where girls of 13 are on an average nearly 3 lb heavier than boys of that age. The condition of enlarged tonsils and adenoids (not differentiated) was diagnosed in 21 7 per cent of the boys and 23 4 per cent. of the girls An abnormally large proportion in a group of cases was found among children habitually taking their dinner at school because of distance from their home or for some private reason the prevalence among these children was three times as great as among those who go home The connexion of this condition with deafness was shown by the fact that out of 516 cases of defective hearing in 28·2 per cent. enlarged tonsils were present It is gratifying to hear that care of the teeth is becoming general the demand for toothbrushes almost exceeding the supply provided by the Education Committee.

Owing to war conditions the routine medical inspection of school children in *Norfolk* during 1915 had to be suspended in April Matters requiring urgent attention and the management of outbreaks of infectious disease also the examination of children specially brought forward by the teachers as needing medical care, were dealt with by Dr J T C Nash the county medical officer of health, personally during the remainder of the year His report deals with a total number of 3847 children submitted to the routine examination

Of these children 86 93 per cent. were well nourished and in only 0·18 per cent was the nutrition actually bad. All the children were clean except 1 5 per cent and in only one child were body vermin found to be present Organic heart disease was diagnosed in 0 18 per cent and non pulmonary tuberculosis in 0 32 per cent. Not a single case of tuberculosis of the lungs was definitely diagnosed and in only one child was it suspected Defective vision (less than 6/9 in either one or both eyes) was found in 7·93 per cent. The provision of X ray treatment for ringworm being impracticable, systematic application of mercurial ointment was carried out in a ringworm class of 33 children with such good effect that at the end of the year there were only two children still uncured

In *Northamptonshire* the work of medical inspection in 1915 was carried out by Miss M J Keers M B , after the departure of Dr J H Mason on military service in April , 4571 children were systematically examined

Of these 95·4 per cent. were well nourished and only one child was considered to be actually in a state of malnutrition 95·4 per cent also were clean and in only three instances were body vermin detected Organic disease of the heart was present in 0 59 per cent. and pulmonary tuberculosis in 0 46 per cent other forms of this latter disease being found in 0 24 per cent Normal vision was present in 67 per cent of the 1898 children tested The weights of the boys (73½ lb) and girls (73½ lb) in the urban districts at 12 to 13 years of age were practically equal in the rural districts the corresponding figures were 74¾ lb for the boys and 77¼ lb for the girls In concluding his report Mr Charles E Paget the county medical officer notes that owing to the war a larger number of children than usual have failed to receive treatment especially in respect to defective vision and throat cases

In *Warwickshire*, during the early part of 1915, the routine medical inspection of 1979 school children was carried out in addition to special examinations, after June 1st, owing to war conditions only children specially selected by the teachers and health visitors were examined, to the number of 1112

A considerable proportion of defects was found in these special cases treatment of which was undertaken with benefit the interruption of the routine inspection though making a regrettable hiatus in the progressive improvement of the health of the school children in the county was probably unavoidable Verminous heads and ringworm give a good deal of trouble and treatment of these cases in rural districts is full of difficulty as the distance from the nearest practicable treatment centre is often considerable No scheme for the provision of treatment by the county council of defects found in school children has yet been adopted Dr Bostock Hill mentions the difficulties that have been experienced in carrying on the work of medical inspection on account of the war and is satisfied with the results that have been obtained Of the 1979 children examined as entrants and leavers nutrition was below normal in 15 2 per cent. being actually bad in only 0 4 per cent.; body cleanliness was unsatisfactory in 4 1 per cent organic heart disease was detected in 0·9 per cent, and pulmonary tuberculosis in only 0 1 per cent

The report on school medical inspection in the *West Riding of Yorkshire* in 1915 is very short on account of the absence of nine of the medical staff (including Dr J R Kaye, the school medical officer) on military service The work has been maintained in spite of difficulties due to this cause The number of scholars on the school roll was 200 513, of whom 38 023 were examined at the routine inspections, besides 18 971 *special cases*

Of the routine cases—entrants intermediates and leavers—0·18 per cent. were poorly nourished and 14 26 per cent. were verminous as regards the head Pulmonary tuberculosis was diagnosed in 0·23 per cent. and other forms of tuberculosis in 0 38 per cent Of the whole number of children—entrants intermediates, and leavers—26 70 per cent were unvaccinated of the entrants the proportion was 45·60 per cent of the leavers 14 69 per cent These figures speak for themselves At 17 secondary schools the entrants were inspected of ages 11 to 14 17 14 per cent. were unvaccinated and 6 31 per cent. were verminous It is unfortunate that several of the care committees have ceased to exist, leaving in their respective districts the whole visiting work to be done by the school nurses

URBAN VITAL STATISTICS

(Week ended March 31st 1917)

English and Welsh Towns —In the 96 English and Welsh towns with an aggregate civil population estimated at nearly 18,000 000 persons, the annual rate of mortality was 17 7 against 18·5 and 16 5 per 1000 in the two preceding weeks In London with a population exceeding 4 000 000 persons, the death rate was 17 8, or 0·3 per 1000 above that recorded in the previous week among the remaining towns the rates ranged from 4 7 in Ealing 5 4 in Acton and 8 4 in *Oxford to* 24 5 in Bolton 24 7 in Rochdale and 25 5 in Plymouth The principal epidemic diseases caused 406 deaths which corresponded to an annual rate of 1 2 per 1000 and included 252 from measles 57 from whooping-cough 43 from infantile diarrhœa, 41 from diphtheria 10 from scarlet fever and 3 from enteric fever The deaths from measles showed a further increase compared with the numbers recorded in the nine preceding weeks and caused the highest annual death rates of 3 3 in Plymouth and in South Shields, 3·9 in *Ilford* 4·0 in Walsall and 7·2 in Dudley The 795 cases of scarlet fever and the 1377 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 22 and 100 below the numbers at the end of the previous week Of the 5866 deaths from all causes in the 96 towns, 181 resulted from violence The causes of 54 of the total deaths were uncertified of which 11 were registered in Birmingham 8 in Liverpool and 4 each in London Manchester and South Shields

Scotch Towns —In the 16 largest Scotch towns with an aggregate population estimated at nearly 2,500 000 persons the annual death rate was equal to 17·9 against 18 3 and 16·2 per 1000 in the two preceding weeks The 418 deaths in Glasgow corresponded to an annual rate of 19·5 or 3·2 per 1000 above that recorded in the previous week and included 23 from whooping-cough 16 from measles 5 from infantile diarrhœa, 3 from diphtheria, 2 from scarlet fever and 1 from enteric fever The 116 deaths in Edinburgh were equal to a rate of 18 2 per 1000 and included 7 from whooping-cough 5 from measles 2 from infantile diarrhœa and 1 each from scarlet fever and diphtheria.

Irish Towns —The 172 deaths registered in Dublin were equal to an annual rate of 22·5 or 3 8 per 1000 below that recorded in the previous week and included 17 from measles 7 from infantile diarrhœa and 1 each from whooping-cough and diphtheria. The 133 deaths in Belfast were equal to a rate of 17 6 per 1000 and included 4 from measles 2 each from enteric fever and infantile diarrhœa and 1 from scarlet fever

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

To be Temporary Surgeon F A. Knott

The following appointments have been notified —Fleet-Surgeon A. Woollcombe to *Pembroke* Temporary Surgeons R W Townley and J L *Pringle to Pembroke*

ROYAL NAVAL VOLUNTEER RESERVE

J T Wood, L D S, to be temporary Dental Surgeon

ARMY MEDICAL SERVICE

Col H A Bruce Canadian A M C to be temporary Colonel

TERRITORIAL FORCE

To be Deputy Assistant Directors of Medical Services Major W E Miles and Capt H Pinto-Leite

ROYAL ARMY MEDICAL CORPS

A J J Johnston, Surgeon General R A (ret.) to be temporary Lieutenant Colonel

Temp Major A. G P Gipps *to be temporary* Lieutenant-Colonel

Temp Major E Webb-Johnson D S O to be acting Lieutenant Colonel whilst commanding a General Hospital

Captains to be temporary Majors L J Rhea Canadian A.M C, N B Gwyn Canadian A.M C C Wollard Canadian A.M C and S R *Harrison* Canadian A.M C

To be temporary Majors: Temp Capts W P Yetts and Wilford V Robinson (whilst commanding troops on a hospital ship), E O Stabb (while employed at the Manor County of London War Hospital)

T G Moorhead to be temporary honorary Major

Temp Capt C G G Keane to be Lieutenant and to be granted the rank of temporary Captain

Temp Capt. J D Gimlette relinquishes the rank *of* temporary Major on reposting

The undermentioned are granted temporary honorary rank whilst serving with No 22 General Hospital —As Lieutenant-Colonel: H Cabot As Major G C Shattuck E G Crabtree As Captain E S Bridges As Lieutenant E D Busby E S Welles F B Grinnell E S Fish

To be temporary Captains Lieut T C Bowie and C Robinson Temp Lieuts E H Wheeler and F G Thomson and F S B Fletcher S G Billington H S Berry G B Flux B N Murphy M C late Captain R A.M C

To be temporary Lieutenants H McLean R G Maglione R Appleton S W Milner J E Mitchell J B Wilkie G McNeill, H C Quirke T McFetridge W L. G Anderson, H C W Wood W G Attenborough A G Stewart R B Fletcher J G B Smith E A. Price N Glegg W H Miller C P A. Stranaghan P Murphy R J Croxford A E Baron E C Tamplin F Jubb Temp *Hon* Lieut T B Johnston A M Caverhill L N Morris C H Wagner T B Davies H L Blackley A Armer J B McDougall D S Clarke, J B Ball N S *Lucas* D Young A. A. Wilkinson H E Graham R A. Campbell H Bardsley A W Hare W L. M Day E Wragg G Nelson, D W Anderson

Officers relinquishing their commissions Temp Capts D Lawrie and T J S Moffett, Temp Lieuts D C Wilson W J Greeby and *C B* Richardson and Temp Hon Lieut. W H Thomas (having ceased to be employed with the British Red Cross Society in France)

SPECIAL RESERVE OF OFFICERS

Lieutenants *to be* Captains: D R Hennessy J A. C Kidd S J V Furlong J Y McLean D Roger

A H Mitchell from Aberdeen University Contingent, O T C and J R John from London University Contingent O T C to be Lieutenants

Capt W J Reid relinquishes his commission

TERRITORIAL FORCE.

Major E C M Foster to be acting Lieutenant-Colonel whilst commanding a *Field Ambulance*

Major W E Miles is restored to the establishment on vacating the appointment of Deputy Assistant Director *of* Medical Services.

Capt T S Allan to be temporary Major whilst in command of a Military Hospital

Capt. H Pinto-Leite is seconded while holding the appointment as Deputy Director of Medical Services.

To be Captains: Cap A J W Stephen (from Northern General Hospital) and Lieuts J S Cooper J B Hogarth, H England P G Phillips

Lieutenants *to be* temporary Captains whilst serving with the Medical Unit of the University of London Contingent Senior Division O T C: J H Ryffel and W Wright

A G Harrington to be Lieutenant

Capts A J Archibald and W Love relinquish their commissions on account of ill health Capt W J Deighan relinquishes his commission on account of ill health contracted on active service and is granted the honorary rank of Captain Capt F W A. Stott Attached to Units other than Medical Units relinquishes his *commission* on account of ill health

VOLUNTEER FORCE.

A. F Turner (late Lieutenant 2nd V B Gloucestershire Regiment) to be temporary Captain and Medical Officer 3rd Battalion Gloucestershire Volunteer Regiment

INDIAN MEDICAL SERVICE

Lieut Col H B Melville on return from leave has been posted to Gorakhpur as Civil Surgeon Brevet Col H F Cleveland has been appointed Deputy Director General vice Lieut. Col F E Swinton and Lieut Col James has been elected a member of the Punjab Medical Council Capt R H. Bott has been elected an ordinary Fellow of the University of the Punjab

Col le Bel the chief doctor of the French Canadian Hospital at St Cloud has been presented with the Cross of the Legion of Honour

"Audi alteram partem

"SOLDIER'S HEART"

To the Editor of THE LANCET

SIR,—The remarks of Captain Adolphe Abrahams[1] and the comments of Dr Thomas Lewis have much interested me, and perhaps I may be pardoned for again trespassing upon your space

The opinion of both Captain Abrahams and of Dr Lewis upon cardiac strain seems to me to be particularly valuable Although I cannot lay claim to the athletic distinction of Captain Abrahams, yet I have been capable of prolonged and strenuous exertion, and having been at the same time interested in morbid affections of the heart, naturally I have paid some attention to the effect of exercise upon the heart As an illustration of the fact that I have at times put my own heart to more or less severe tests, it may be mentioned that although I have long passed the age of youth, in the month of April preceding the outbreak of war I rode on an ordinary "push bicycle" from Taz malt in Algeria to Algiers, a distance of 179 kilometres (112 miles) in nine and a half hours, although my low gear was out of order and could not be used All the hills were ridden some of them no mean ones, and the ride ended over a road paved for six or seven miles with cobble stones The ride also happened to have been during an unusually hot spell of weather for the month of April I was told that the thermometer on the day of my ride had registered 98° F in the shade in Algiers at one hotel

While it has not fallen to my lot to meet with opportunities upon which to base an opinion regarding the question of cardiac strain such as have fallen to Sir Clifford Allbutt and to Captain Abrahams, it has always appeared to me that an "athletic heart," if it occurs at all, must be so rare as to require to be classed under the heading of medical curiosities rather than of pathological conditions worthy of serious attention Yet during an experience in the post-mortem room covering about 2500 necropsies I met with three instances of great enlargement of the heart which, by excluding all other possible causes of enlargement, appeared with some reason to have been consequent upon prolonged physical exertion But two of those cases occurred in stokers in gasworks, and the third in a blacksmith It is obvious that in those cases strenuous work was carried on under unusual conditions—namely, under the influence of great heat—and the question arises whether the heat may not have been the more important factor in leading to the cardiac enlargement During heavy work in a hot atmosphere most of the water drunk must be passed off by the skin, comparatively little by the kidneys Toxic products of metabolism may be retained and the heart suffer in consequence A good example of toxic enlargement of the heart, it may be mentioned in passing, is the enlargement which is not so very uncommonly met with as a result of excessive indulgence in alcohol, but alcohol as a cause for enlargement in the above cases was as far as possible excluded

However reasonable or unreasonable my theory may be regarding a toxic causation for enlargement of the heart occurring in association with prolonged arduous work, it is a sufficient supply of fluid that I require to enable me to arrive at the end of a long ride feeling capable of doing as much again Captain Abrahams attributes the warding off of fatigue during one of his physical feats to a good meal It seems to me that if the circulation benefits from the solid constituents of a meal taken during exercise it can only do so because the food acts as a mechanical stimulus to the abdominal vaso-motor system, a stimulus which, of necessity, reacts on the general circulation The muscles can derive no direct benefit from the meal until time has allowed digestion to take place whereas the influence of a meal on the sense of well being is almost immediate Some persons may require abdominal stimulation of the vaso-motor system during strenuous exercise, in others fluid taken in sufficient quantity to make up for the loss of water by perspiration may be all that is necessary It is true that in the above mentioned ride I drank two bottles of sweet lemonade and two large cups of café-au lait containing sugar, and thus took a rapidly diffusible food in the form of sugar, but on several occasions during a ride of nearly 1300 miles in Algeria and Tunisia, including a ride from Algiers to Tunis, I frequently had water only in the course of the day, which fortunately could often be procured clear and fresh in the mountainous and hilly districts

In addition to physical conditions affecting the circulation, as Captain Abrahams points out, the mind also has its influence A child may run about all day after butterflies and show no sign of fatigue, but become hopelessly tired after an hour's dull walk The athlete may have an object in view and feel no fatigue until the object is attained This is not the case with the soldier Most of his exercise is undertaken with no other stimulus than that of fulfilling, it may be, dull duty He is at a disadvantage in another way The athlete's feats are more often than not spasmodic. Consciously or subconsciously, should he overstrain in some measure his physical powers he, by a diminution in outlet of energy, allows time for recuperation The soldier is not his own master in such matters and in the absence of sufficient time for recuperation the nervous balance of the vaso motor system may be upset

The athlete will, I think if he study his own circulation for a day or two after some feat in which he had put a strain upon his physical powers, great even for himself, find some departure of the vaso motor system from its usual smooth working This is most likely to take place when strenuous exercise has not previously been undertaken for some time, but it seems to me that slight temporary disturbance of the vaso-motor system may undoubtedly occur The conditions of life of the athlete are such that he suffers no harm The conditions of the soldier may be otherwise

I am, Sir, yours faithfully,

April 2nd, 1917 THEODORE FISHER.

To the Editor of THE LANCET

SIR,—With Captain Adolphe Abrahams s conception of the "soldier s heart,"[1] with his observation of the aggravation of that condition which frequently appears to result from much attention being called to it in cordaria or in general hospitals, and with his experience of the natural disinclination manifested by some who have suffered from it again to "face the music" of outrageous war my own views and experience largely agree The "defensive neurosis" of which he writes is certainly shown by some, although not by all Others are bravely anxious to resume duty and do so and I have found this even among "gunners," whose 'job,' to use a Service term is more arduous than that of some other branches

The psychical and neural factors, as I have before argued play a large part in some cases of *persistent* soldier's heart but a tedious or protracted form of this condition is met with also in the unemotional and stable man who is physically played out and whose nervous system doubtless manifests changes not otherwise expressible at present than by such terms as the loss of reserve force or exhaustion The prospects of even a young and healthy man, who has escaped invalidism and injury and been actively engaged in modern warfare for 18 months or 2 years and who shows the "soldier's heart" (the advent of which, in some cases, is precipitated by a "shell shock"), of again being able to resume full duty are not good Who can say that such a one has not earned relief from work in the fighting line although there is no release in war? He has "done his bit' and may find useful war work elsewhere than on the stricken field

It is, however, to another point in the heart of the soldier, as distinguished from the "soldier's heart," that I wish now briefly to allude, conceiving the point to be of practical importance Captain Abrahams s remarks, if I may without offence say so, have, on the whole, a commendable reserve and balance, but I would respectfully suggest that as an adherent of the new cardiology—the modern aspect of heart disease, to use the phrase of the last Lumleian lecturer—he has revived, in his contempt for the cardiac bruit, a view which, I had hoped, was fast finding a richly deserved quietus The ' purrs," "barks," "roars," and "squeaks" of the heart are not precisely analogous to the various grunts of an efficient motor car In making this comparison Captain Abrahams doubtless is, however, rhetorical rather than instituting that analogy which has been well called the fruitful mother of *many errors*

---

[1] THE LANCET March 24th 1917, p 442.

[1] THE LANCET March 24th p 442

Many systolic bruits, transient or extracardial in nature, which are usually easily diagnosed and have frequently been fully appreciated, are, of course, negligible But with all due regard for the value of integrity in muscular power (the importance of which, so far as I know, has for long been recognised even by those who find some wisdom in *old* aspects of heart disease) is it contended, may I inquire, that it is an excellence in the cardiac mechanism to possess a defective valvular apparatus? The new cardiologist, who regards with some complacency his additional enlightenment, would appear at times to think so Is the career of a soldier one to be chosen by those who possess even a mitral lesion which has survived with impunity the calls of civil life and shows when examined no material enlargement or dilatation of the organ? Experience answers, Certainly not Organic valvular disease, direct and reflux, which has been overlooked or ignored, and notwithstanding exceptions to the rule has frequently been found to lead to hopeless invalidism, and at times even to the death of the soldier So well established is this fact that no medical officer, however "modern" his outlook on heart disease would be justified in subjecting the bearer of such a lesion to the exertions and vicissitudes of the soldier's life in war It is to emphasise again this point, on which a considerable experience enables me to speak with conviction that I write these lines Fortunately, the Army Medical Service as a whole, and in spite of "modern" conceptions continues to prefer an entire to a broken pump in the circulation, even when the break is only in the wash leather

I am, Sir, yours faithfully,

ALEXANDER MORISON

Upper Berkeley-street, W April 2nd 1917

THE LUMLEIAN LECTURES ON HEART DISEASE

To the Editor of THE LANCET

SIR,—There is one point in the modern study of heart disease which I think, hardly meets with the recognition that it deserves, and I venture to believe that in the future it will greatly alter the attitude of the medical profession to this study It is this that we can from the most frequent cause of heart disease in this country not only isolate the exciting cause, but reproduce the lesions, and thus the rheumatic heart is proved to be an infective process From the date of this acquisition to our knowledge I hold that much teaching on the subject of heart disease has been entirely altered So far as cardiac infections are concerned, we see at once that there are two phases—running of course, the one into the other—the active phase, in which everything ever to be gained in the way of cure must be sought for and the stage of scar formation, in which palliative measures are only possible. Further, we realise that the study of heart disease is not, as would so often appear to be thought, a study of the heart alone, but a study of the response of the heart to infection correlated with the responses of the other viscera.

It is often enough that the character of the infection, *qua* virulence determines the future of the patient rather than the particular physical signs at the moment To estimate this virulence we must study not the heart alone but the patient The life history of the infection is of more cardiac importance than irregularities of action or valvular lesions Why does the infection, in some cases, linger stubbornly on breaking out at intervals, and producing in this way stenosis? Why do the valvular lesions sometimes fail to heal and thus produce various grades of malignancy? Again, why does the rheumatic infection in some cases damage the nervous mechanism of the heart as in children it does the brain in chorea thus producing intractable cardiac 'neurasthenia'? How much can we influence the development and course of heart disease by more careful attention to angina faucium? What can we do to prevent scar formation by alteration of surroundings and more prolonged convalescence? When are we going to look upon scar formation as a failure in our methods and not as "heart disease" These are problems with which what I venture to call the modern study of heart disease confronts us, these are the problems the solution of which, however imperfect, will lead to the relief of the human race from much affliction Our text-books mostly begin at the end of the story, or perhaps it would be more correct to state that they lavish most of their wisdom on a lost cause There are admittedly very many points in heart disease unassociated with infection, and I have nothing but admiration for the investigations connected with them, but I do claim that the establishment of cardiac infection in rheumatic heart disease is not only modern, but will eventually alter entirely the methods of description of many of the most important developments of heart disease

I am, Sir, yours faithfully,

Devonshire-place, W April 6th, 1917 F JOHN POYNTON

THE EXAMINATION OF THE BLOOD OF TYPHUS FEVER CASES BY DARK-GROUND ILLUMINATION

To the Editor of THE LANCET

SIR,—The infective agent in typhus fever has been a subject of much investigation in recent years In Belfast we have made numerous blood cultures, but have failed to isolate any micro-organism which could be definitely incriminated as the cause of the disease During the past few weeks we have had an opportunity (through the courtesy of Dr Gardner Robb) of examining the blood of typhus fever patients with dark ground illumination. Our investigations are yet far from complete, but the following facts seem worthy of putting on record

1 In all cases examined before the crisis the blood shows a well defined slender body which is about the thickness of the *B typhosus* and like the latter, is of variable length This body is extremely pliable, wriggles, and shows distinct motility In some cases its length is about 4μ, in others 6–8μ, and often a long slender filament about 16μ is seen The clean cut outline and the motility and the characteristic appearance indicate its parasitic character and differentiate it from any artefact Whether it should be classed as a bacillus or spirochæte must be decided by further study The appearance in the dark field is such as is presented by ordinary bacilli but the longer forms are not unlike the straighter forms of the *Spirochæta ictero hæmorrhagica* Against the view that it is a bacillus is the fact that our cultures so far have been completely negative It is remarkable that blood which contains numerous living forms of above description inoculated on all kinds of media both under aerobic and anaerobic conditions shows no growth The micro-organism at each pole shows a highly refractile granule, and its slender pliant body differentiates it from the diphtheroid bacilli described by Plotz and others

2 The micro-organism is free in the plasma If the citrated plasma is centrifrugalised and the deposit examined in the dark field the presence of the germ is readily detected but as a rule there is no difficulty in finding it without this procedure. Since the disease is transmitted by lice it is obvious that the virus must be present even in a small drop of blood

3 The presence of above germs in blood which gives no growth on ordinary media is diagnostic of typhus fever

4 So far we have examined blood from 12 separate cases of very different ages and in all have found the micro-organism The day of the disease at which blood was examined varied from the fifth to fifteenth During convalescence the germ could not be detected in several specimens, though it had been found at the acute stage

In conclusion we may state that a very careful examination of five specimens of normal blood showed no bodies at all resembling the above We used Leitz s dark ground condenser, 1/6 objective lens and 4 ocular, and as a source of illumination Mill's electric arc lamp We need hardly add that slides coverslips &c, were scrupulously clean and sterile In our opinion the micro-organism is closely related to the *Spirochæta ictero-hæmorrhagica* and to the bacillus found by Wolbach in Rocky Mountain fever, and pending further investigation might be described as the *Spirochæta typhi*—We are, Sir, yours faithfully,

W JAMES WILSON,
GEORGINA R DARLING

Hygiene and Public Health Laboratories Queen's
University Belfast April 6th 1917

THE CLOSURE OF COLOTOMY OPENINGS

To the Editor of THE LANCET

SIR —In his letter in your issue of April 7th Mr Lockhart-Mummery still maintains that the enterotome method of closing a colotomy opening is the best He objects to the method of Greig Smith on the ground that—

> "The extraperitoneal operation is very liable to leave a weak place in the abdominal wall, and many patients have subsequently to wear belts It also leaves a condition which is not normal and is liable to cause trouble later"

In his paper in your issue of March 10th, in discussing the enterotome method, he states

> 'The only objection to it is that the condition left is not quite normal, as the bowel remains attached to the abdominal wall, and there is often a weak spot which may necessitate the wearing of a belt or support"

Wherein lies the difference?

I have seen no trouble subsequent to the extraperitoneal operation Mr Lockhart-Mummery condemns the extraperitoneal method as being dead but in doing so condemns his enterotome method He wrote his paper feeling that as surgeon to St Mark s Hospital he should call the attention of the uninitiated to the best method of closing colotomy openings The enterotome method he regards as "the easier and by far the safer" when compared with the resection method He must admit the same for the extraperitoneal method, as from his own statements he has no more objection to it than he has to the enterotome method

His paper was also written to describe "(1) the easiest and (2) the best methods of closing a colotomy" A third object might have been the safest method The statistics given by him show by his methods 14 per cent deaths and 16 6 per cent failures after repeated operations The figures I gave in my letter of March 31st show for the extraperitoneal method 2 6 deaths and no failures I think that even Mr Lockhart Mummery should agree that the extraperitoneal method is the one to be adopted by the less initiated, the resection method being kept for the unusual case and the enterotome put into the museum

A point which has not apparently been made clear is, that there must be adequate clearing of the bowel before the opening is closed If this is done, what can be the object of having the bowels opened on the second day? It will cause undue tension on the sutures There are no masses of hard fæces in the bowel Even if there were hard masses of fæces present due to faulty preparation, then a small enema or small doses of salts will not break them up, The stimulus will only cause them to come into the neighbourhood of the sutures, a condition of things which, I agree with Mr Lockhart-Mummery, is to be avoided at all costs In my opinion, routine opening of the bowel on the second day will cause failure in the closing of colotomy openings

I am Sir, yours faithfully,

ERNEST FINCH, M D, M S Lond F R C S Eng,
Assistant Surgeon Royal Infirmary Sheffield

April 9th 1917

TUBERCULOSIS AND THE WAR

To the Editor of THE LANCET

SIR,—In reply to Dr Edward E Prest's letter in THE LANCET of March 24th as a believer that a good deal of the trouble in the comparison of tuberculous cases is due to the inexact use of terms, I should be glad to know what he means by ' that he may be permanently cured," and how the condition is recognised when it is attained, as after much inquiry I have up to date failed to find a satisfactory description of how it may be achieved and recognised

In connexion with his desire to give five months' treatment in a sanatorium to cases classified as Class I, I may state that I have had two cases sent to my sanatorium this week from the Army which illustrate the point One patient came from India, there was T B bacillus found in the sputum months ago when his condition of health was very low He is now his normal weight, he has no temperature variation (taken rectally) no increase of pulse rate no cough no sputum, desires and is quite capable of working after a short holiday Should I send him to "a properly conducted sanatorium'? The other case was discharged from my sanatorium 20 months ago, apparently all active symptoms having subsided and in excellent health He has now been returned from France after 12 months' service, 1 stone heavier than when he left, with no cough, no sputum, no increase in pulse rate, and no variation of temperature He is much amused at his success in getting his discharge and pension He is a very efficient "*swinger of the lead*," as I know from experience, and he will remain in the sanatorium as long as we are willing to keep him and would thoroughly enjoy "five months' treatment"

I fully believe in sending Class I cases into a sanatorium if they show any loss of resistance during dispensary attendance, in fact very few others are admitted here except soldiers' dependents or cases forwarded by the War Office, but from watching a considerable number of cases (about 2000) I am satisfied that there is a stage anterior to that requiring the complete cessation of wage earning, which the sanatorium treatment necessitates Any threat to their resistance by the tubercle organism can be countered without turning them into invalids, even temporarily This stage takes a certain amount of care in recognising, and is generally classified as incipient phthisis When a sanatorium is indicated the lesion has usually become more definite and permanent tissue destruction has occurred as is demonstrated by the physical signs of the grosser nature easily recognised by the ordinary stethoscope

More than 50 per cent of the cases that have been passed through the sanatorium here in the last two years are in full work, many for a considerable time without deterioration. Still I should hesitate to describe them "as permanently cured," and it is considered advisable that they should still attend the dispensary occasionally for observation and advice

I am Sir, yours faithfully,

Middlesbrough April 4th 1917 HENRY A ELLIS

READING BY EAR

To the Editor of THE LANCET

SIR —Will you permit me to point out that the article in the *Times* of March 29th describing a recent trial of the optophone was of a somewhat misleading character On Jan 25th Dr d'Albe undertook to give a demonstration of the practical value of the optophone before some experts of the National Institute for the Blind, this demonstration to consist of the reading of newspaper type at the rate of 25 words a minute It was deferred until Dr d Albe had practised to a degree which he considered sufficient on the instrument to be employed Dr d Albe selected March 26th as the date, and I have it from him that he had practised 130 hours on the optophone used

As to how far short he fell of his expectations the following extract from a report submitted to me by the four experts of the National Institute for the Blind who attended the demonstration, and two of whom were blind men, will show

> The speed which the inventor was able to attain—one word in one minute and a quarter—would be utterly useless Dr d'Albe's contention that increased speed was purely a question of practice is not convincing, for our knowledge of the optophone leads us to believe that the speed must always be so slow and the use of the instrument so nerve-racking as to make the optophone of little or no value to blind people, whatever may be its use in other directions But even assuming that a satisfactory speed could be obtained, the expensive character of the instrument would put it out of the reach of the average blind person

I hope that Dr d Albe will now cease to issue misleading statements with regard to the practical value of the optophone as a means of enabling blind people to read It can at present be only described as an interesting scientific toy It is to be most sincerely hoped that Dr d Albe will in the course of time succeed in producing results from his ingenious invention which will render it worthy of serious consideration by those who have the interests of the blind at heart

I am, Sir, yours faithfully,

ARTHUR PEARSON
President, National Institute for the Blind

Great Portland street, London W April 2nd 1917

⁂ We noted on Feb 17th Dr d'Albe's demonstration of the optophone at the Röntgen Ray Society and his claim that with practice printed type could be read at the rate of several words a minute This claim he appears to have failed to establish —ED L

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Wounded

Major J S Jenkins Canadian A.M C
Capt A. Peden, R A.M.C
Capt P R. Bolus, R A.M C
Capt J G Greenfield, R.A.M C , attached Cameronians
Capt G F Hardy, M C , R A M.C attached Royal Garrison Artillery
Capt J Hardie, Australian A.M.C
Capt F R Sturridge, R.A M.C , attached Royal Sussex Regiment
Capt. J A. R Wells R.A.M C attached Lancashire Fusiliers
Capt V E Badcock R.A.M.C , attached Highland Light Infantry
Capt C H. Fischel R A M C , attached Royal Field Artillery
Capt R P Rosser R A.M.C
Capt A. A. Rutherford, R A.M C

Missing

Capt S J Linzell, R A.M C

DEATHS AMONG THE SONS OF MEDICAL MEN

The following sons of medical men must be added to our lists of those who have fallen during the war —

Second Lieut R B W Gosse, Cheshire Regiment attached Royal Warwick Regiment second son of Dr H. W Gosse, of Eccleshall Staffs

Lieut F C Woods Royal West Surrey Regiment, younger son of the late Surgeon Major Woods, A.M S

MENTIONED FOR WAR SERVICES

The name of the following medical officers are to be added to the list given in THE LANCET of March 3rd p 353 —

Temp Col. J Atkins C M G A.M.S Temp Capt W T Finlayson R.A.M C Surg Lt Col. and Hon. Surg -Col D Hepburn R.A.M C Major (temp. Lt Col) G S Mansfield Reserve of Officers R.A.M C Temp Capt C R Stewart R A.M.C Temp Major R H Swan R.A.M C Major and Bt Lt -Col. C R Sylvester Bradley R.A M C Temp Capt D J Thomas R.A.M C Lt. Col. F H. Westmacott R.A.M.C

The following corrections in the list given in THE LANCET of March 3rd are announced —

For Lt -Col J Battersby read Lt Col H. L. Battersby for Maj E Grey read Maj E Gray for Maj J H H. Pirie read Maj W H. Pirie for Davies, Temp Capt. F J P., read Daly Temp Capt F J P

THE CENTRAL MEDICAL WAR COMMITTEE THE SUPPLY OF MEDICAL OFFICERS FOR THE ARMY

At a meeting of the Central Medical War Committee, held on Wednesday April 11th a report by the Assessment Subcommittee was read showing how it was proposed to meet the demands of the War Office for further medical officers

The report stated the position was as follows—that of the number of medical officers required by the War Office by May 31st some 250 men were still wanting and that as the first step towards making up this deficit it had been decided to include in a further call men between 41 and 45, men passed for home service only and men who having served with the Army have returned to civil practice for not less than one year this being in addition to any men under 41 who could still be spared from the districts in which they practised

The Assessment Subcommittee proceeded by dividing all the material possibly available into three groups—namely areas which cannot under existing circumstances supply more medical men, areas in which it is not possible to say that this disability definitely exists, and lastly, areas on which a call can be made immediately Under this third group were included those areas and sub-areas in which more medical men are now available by an increase in their number since the last call was made or by the raising of the age limit Having made careful analysis of the sources of supply in minute detail the Assessment Subcommittee in the report considered that the new call which it proposed would make good the estimated deficit in the number of medical officers demanded by the War Office by May 31st

The report of the Subcommittee, after debate, was approved in a resolution of the following terms —

1 That the Committee approves the report of the Assessment Subcommittee as to the prospects of meeting the requirements of the War Office for May 31st, and authorises calls to be made forthwith in accordance therewith 2 That on the facts ascertained from the critical review now made of the remaining provision for the civil community the Committee records its opinion that no further substantial reduction in the number of doctors in civil practice can be effected without such public dissatisfaction as, in the opinion of the Committee, should not be occasioned on its sole responsibility, it therefore deems it its duty to place the position before the Government through the departments with which it is chiefly brought into relation—namely, the War Office, the Local Government Board, and the Insurance Commission

At a recent meeting of the Executive Committee of the Wandsworth Division of the British Medical Association, a resolution was unanimously carried protesting against any measure of compulsion being applied to the medical profession which is not at the same time applicable to the whole community

THE MEDICAL SERVICE OF THE UNITED STATES NAVY

America's momentous decision to take a part in the war gives special interest to an illustrated article dealing with the United States Naval Medical Service which appeared in the *New York Medical Journal* of March 17th Before the passing of the Act of August 29th, 1916 which provided for a large increase in the personnel the Medical Corps of the United States Navy consisted of 345 medical officers The full complement is now 683 and there are stated to be about 300 vacancies The limits of age for appointment are 21 to 32 years, and, as in our own naval service, candidates have to pass both a physical and a professional examination No candidate is accepted unless his physical condition warrants an expectation of active service until the retiring age of 64 years when he receives two-thirds of the pay of his grade The professional examination is divided into two parts the first being for enrolment in the Naval Reserve Force. If successful the candidate attends a course of instruction at the Naval Medical School on full pay and allowances, upon the completion of which he takes the final examination for appointment in the Medical Corps of the Navy The pay of an assistant surgeon on shore duty is $2000 per annum with quarters, or, when quarters are not supplied by the Government, an additional allowance for quarters amounting to $432. At sea the assistant surgeon receives $2200, his quarters and attendance being furnished him aboard his ship Every five years the pay of an officer increases by 10 per cent , although the increment cannot exceed 40 per cent , calculated on the annual base pay of his grade. The pay of a medical director with the rank of captain is thus limited to $5000 that of a medical inspector with the rank of commander to $4500 and that of surgeon with the rank of lieutenant commander to $4000 The pay of a medical director with the rank of a rear admiral is $6000 for the lower half and $8000 for the upper half of those in that grade

In addition to the regular Naval Corps there is a medical division of the Naval Reserve Force which requires 500 surgeons, membership being open to all medical men under 44 years of age who are American citizens A member receives two months' retaining pay for every year of his enrolment in addition to service pay for any term of actual service which he may give the pay corresponding to that for similar ranks in the Navy Members who re-enrol for four years, subject to certain conditions, receive an increase of 25 per cent of their base retaining pay After 20 years service an officer may be retired on his own application with a cash credit equal in amount to his retaining pay during the last term of enrolment In order to meet the need for rapidly training reserve officers in the duties of medical recruiting during mobilisation a correspondence course has been established at the Naval Medical School, Washington D C

MEDICAL ARRANGEMENTS IN VOLUNTEER BATTALIONS.—A question addressed to the Under Secretary of State for War last week in the House of Commons elicited the fact that the appointment of medical officers to volunteer battalions has been sanctioned by the War Office. It has not yet proved possible to proceed with the formation of volunteer field ambulances, owing to changes of organisation consequent on the passage of the Volunteer Act Proposals were, however, under consideration, and Mr Macpherson hoped that the matter would shortly be settled

The Army Doctor's Risks —In the House of Lords last week, when the Military Service (Review of Exceptions) Bill was read a third time and passed, Lord Derby said it was impossible to set up medical appeal boards all over the country, as was asked for in the House of Commons, because there were not sufficient doctors to do the work. Some people, he said, thought that the work of the Royal Army Medical Corps was free from danger, but, as a matter of fact the Army lost more than 400 doctors killed and wounded in the Somme battle alone At the present moment, he added, the Army was not critically, but certainly lamentably, short of doctors

Medical News.

Examining Board in England by the Royal Colleges of Physicians of London and Surgeons of England —At the Second Professional Examination of the Conjoint Board in Anatomy and Physiology, held on March 28th and 29th and April 2nd, 52 candidates presented themselves, of whom 30 were approved and 22 were rejected The following are the names of the successful candidates —

* Awarded a mark of distinction

N B —This list, published for the convenience of candidates is issued subject to its approval by the Senate

University of Durham Faculty of Medicine —At the Convocation held on March 31st the following degrees were conferred —

Doctor of Medicine —Idris David Evans and Robert Peart

Bachelor of Medicine (M B) —Norman Braithwaite Ernest Bramley Richard Vere Brew Stephanie Patricia Laline Hunte Taylour Daniel Donald Henegan James Dixon Johnson John Kerr Ritchie Landells, Kamel Ibrahim Shalaby Charles Rees Smith and Iskander Soliman

Bachelor of Surgery (B S) —Norman Braithwaite Ernest Bramley Richard Vere Brew Horace George Bennett Dove Donald Henegan John Kerr Ritchie Landells, Kamel Ibrahim Shalaby and Charles Rees Smith

The following received the Diploma in Public Health (D P H) —

Richard Julius Cyriax and Douglas Catterall Leyland Orton

The following received the Licence in Dental Surgery (L D S) —

Wilfred Phillipson Spence

Through a decision of their Joint Matriculation Board the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham have now come into line with other examining bodies in not requiring that Latin should be taken as an obligatory subject in the entrance examination to the Faculty of Medicine

Royal College of Physicians of London —An extraordinary Comitia of the College was held on April 2nd Dr Frederick Taylor, the President, occupied the chair and delivered the presidential address, in the course of which he first mentioned the changes in the College list, among them that the College had lost by death during the year 6 Fellows, 8 Members, 1 Extra licentiate and 195 Licentiates Among the 8 Members was the senior Member, Dr Horace B Dobell, who founded the lecture which bears his name A long and interesting list of honours, military and civil, conferred upon Fellows, Members, and Licentiates of the College was then read out, after which the lectures delivered during the past year were mentioned—namely, the Harveian Oration, by Sir Thomas Barlow, the Bradshaw Lecture, by Dr H W G Mackenzie, the FitzPatrick Lectures, by Dr W H R Rivers, the Horace Dobell Lecture, by Dr H R Dean, the Lumleian Lectures, by Dr G A Sutherland, the Goulstonian Lectures, by Dr C H Miller, and the Oliver Sharpey Lecture, by Dr C Bolton The medals and scholarships awarded were next referred to, the fact that there were no candidates for the Murchison scholarship being announced After reviewing the principal matters which had come before the President, the Comitia, and the various boards and committees the President read obituary notices of the six Fellows who had died during the year—namely, Sir Lauder Brunton, Bart, Dr William Orange, C B, Dr Duncan Burgess, Dr W W H Tate, Dr William Cayley and Sir James F Goodhart Bart A ballot was taken for the office of President, and Dr Taylor was re-elected After some formal business the Comitia was dissolved

Royal Institute of Public Health —A second course of lectures and discussions on Public Health Problems under War and After war Conditions" will be held in the lecture hall of the Institute on Wednesdays from April 18th to July 25th inclusive, at 4 P M The lectures range over a large area of immediately pressing topics, each of which is to be dealt with by an acknowledged expert, and discussion will follow the delivery of the lecture Medical officers of health, medical practitioners, sanitarians, and others engaged in public health work are invited to attend A syllabus of the course may be obtained on application to the secretary, 37, Russell square, London, W C 1

METROPOLITAN ASYLUMS BOARD DIPLOMA IN PUBLIC HEALTH —A course of lectures and demonstrations (lasting three months), in hospital administration will be given at the North Western Hospital, Lawn road, Hampstead, London, N W, by Dr J E. Beggs, medical superintendent, on Tuesdays and Fridays at 5 P M, beginning Tuesday, May 8th The fee for the course is £3 3s, and further particulars may be obtained from the Clerk to the Metropolitan Asylums Board, Embankment, London, E C 4

INSTITUTE OF HYGIENE —The Principal of the Institute, Mr J. Grant Ramsay, delivered on March 29th a lecture on "*The Problem of Food, Fitness and National Resources*" Proper feeding was, he said, the foundation of fitness He had come across strong healthy people in the worst slums of Europe, but always found that they were well fed, he had never met or heard of healthy people even living in the best surroundings, who were badly fed. Proper feeding, however, did not necessarily mean high feeding or large feeding, it meant eating the right foods, in the right quantity, at the right time, and in the right way Halliburton had advocated the eating of rather more than was actually essential, while Chittenden believed we were healthier with rather less than the accepted standard. Nature was very accommodating, and there was much to be said for both theories, but we had followed Halliburton so long that we could now afford to give Chittenden a chance. Those who could afford to do so should continue to buy the best foods and the best parts, leaving the food of the poor as far as possible to the poor, who were more influenced by habit, and would continue to buy what they had been accustomed to

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor not later than 9 o clock on the Thursday morning of each week, such information for gratuitous publication.*

Through a decision of their Joint Matriculation Board the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham have now come into line with other examining bodies in not requiring that Latin should be taken as an obligatory subject in the entrance examination to the Faculty of Medicine

Royal College of Physicians of London —An extraordinary Comitia of the College was held on April 2nd Dr Frederick Taylor, the President, occupied the chair and delivered the presidential address, in the course of which he first mentioned the changes in the College list, among them that the College had lost by death during the year 6 Fellows, 8 Members, 1 Extra-licentiate, and 195 Licentiates Among the 8 Members was the senior Member, Dr Horace B Dobell, who founded the lecture which bears his name A long and interesting list of honours, military and civil, conferred upon Fellows, Members, and Licentiates of the College was then read out, after which the lectures delivered during the past year were mentioned—namely, the Harveian Oration, by Sir Thomas Barlow, the Bradshaw Lecture, by Dr H W G Mackenzie, the FitzPatrick Lectures, by Dr W H. R Rivers, the Horace Dobell Lecture, by Dr H R Dean, the Lumleian Lectures, by Dr G A. Sutherland, the Goulstonian Lectures, by Dr C H Miller, and the Oliver Sharpey Lecture, by Dr C Bolton The medals and scholarships awarded were next referred to, the fact that there were no candidates for the Murchison scholarship being announced After reviewing the principal matters which had come before the President, the Comitia, and the various boards and committees the President read obituary notices of the six Fellows who had died during the year—namely, Sir Lauder Brunton, Bart, Dr William Orange, C B, Dr Duncan Burgess, Dr W W H Tate, Dr William Cayley and Sir James F Goodhart Bart A ballot was taken for the office of President, and Dr Taylor was re-elected After some formal business the Comitia was dissolved

Royal Institute of Public Health —A second course of lectures and discussions on "Public Health Problems under War and After war Conditions" will be held in the lecture hall of the Institute on Wednesdays from April 18th to July 25th inclusive, at 4 P M The lectures range over a large area of immediately pressing topics, each of which is to be dealt with by an acknowledged expert, and discussion will follow the delivery of the lecture Medical officers of health, medical practitioners, sanitarians, and others engaged in public health work are invited to attend A syllabus of the course may be obtained on application to the secretary, 37, Russell square, London, W C 1

Metropolitan Asylums Board Diploma in Public Health —A course of lectures and demonstrations (lasting three months), in hospital administration will be given at the North Western Hospital Lawn road, Hampstead, London, N W, by Dr J E Beggs, medical superintendent, on Tuesdays and Fridays at 5 P M, beginning Tuesday, May 8th The fee for the course is £3 3s, and further particulars may be obtained from the Clerk to the Metropolitan Asylums Board, Embankment, London, E C 4

Institute of Hygiene —The Principal of the Institute, Mr J. Grant Ramsay, delivered on March 29th a lecture on "The Problem of Food, Fitness and National Resources" Proper feeding was, he said, the foundation of fitness He had come across strong healthy people in the worst slums of Europe, but always found that they were well fed, he had never met or heard of healthy people, even living in the best surroundings, who were badly fed Proper feeding, however, did not necessarily mean high feeding or large feeding, it meant eating the right foods, in the right quantity, at the right time, and in the right way Halliburton had advocated the eating of rather more than was actually essential, while Chittenden believed we were healthier with rather less than the accepted standard Nature was very accommodating, and there was much to be said for both theories, but we had followed Halliburton so long that we could now afford to give Chittenden a chance Those who could afford to do so should continue to buy the best foods and the best parts, leaving the food of the poor as far as possible to the poor, who were more influenced by habit, and would continue to buy what they had been accustomed to

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor not later than 9 o clock on the Thursday morning of each week such information for gratuitous publication*

MEDICAL NOTES IN HISTORICAL MANUSCRIPTS THE STUART PAPERS

FOLLOWING are some further excerpts from Part VI of the Stuart Papers The first instalment appeared in THE LANCET of April 7th, p 558

Death of Queen Mary

The Earl of Panmure to the Duke of Mar —1718, May 9 Paris — ' The Queen was taken ill on Sunday the 1st, which I did not know till Monday evening so I went to St. Germains Tuesday morning and Dr Blair went with me They told us there that the Queen was better and that they did not think her in any danger Dr Blair did not then see her nor was his advice asked but on Saturday morning an express came for him so he went to St Germains in all haste, but found her speechless and past all hopes of recovery for she died about two hours after I'm told that Dr Garvan and the King of France's physicians thought she was in no danger the night before and were resolved to have given her physic the next day but I will not enlarge on so melancholy a subject "

Father Gaillard the Queen's Confessor to James III —1718 May 9 St Germains.— ' Il s'agit de vous instruire en detail pour votre consolation premièrement de ce qui s'est passe dans cette sainte mort et secondement de ce qui vous y regarde personnellement par les sentimens que la Reyne m'a marqués a vostre egard et par tout ce qu'elle m'a chargé de vous ecrire Premier article de ce qui c'est passe à la mort de la Reyne Il y avoit quelque temps environ un mois que la Reyne avoit esté attaquée d'un rhûme qui disparoissoit quelquefois et qui de temps en temps se renouvelloit n'estant pas toutafait gueri La Reyne se portoit assez bien le dimanche, premier jour de may feste de St Jaques et St Phillippe. C'estoit le jour qu'elle avoit choisi pour remplir l'heure de son adoration devant le St Sacrement, s'estant associee a la confrairie de parroisse de St Germain Sa Majesté se rendit pour cela a l'eglise de la parroisse cinq heures du dimanche apres disner ayant fait ses devotions a l'ordinaire le matin dans sa chapelle et y ayant recité le rosaire a quatre heures a la maniere accoutumée Le St Sacrement fut exposé à la parroisse des que la Reyne y fut arrivée un peu avant cinq heures La Reyne commenca son adoration à genoux où elle se tint pendant une demiheure, et fut assisse sur ses jambes la demiheure suivante, n'ayant pas voulu s'asseoir sur son fauteuil qui luy estoit preparé L'heure de l'adoration finie le salut fut commencé à six heures auquel elle assista à genoux En suite elle monta dans son carrosse pour s'aller promener sur la terrasse ou elle sentit du froid. C'est ce qui la fit retourner apres demiheure de promenade sans pourtant s'estre trouvee incommodee car elle soupa ce soir la avec plus d'appetit qu'elle n'avoit fait depuis longtemps Elle se coucha a l'heure ordinaire mais elle passa assez mal la nuit jusqu'a cinq heures du matin du lundy qu'elle fut saisie du frisson de la fievre qui dura une heure ce qui fut suivi de la chaleur C'est ce qui fut compte pour peu de chose Je fus apelle et j'eus l'honneur de s'entretenir selon tous les sentimens de sa pieté Cette fievre n'a point cessé jusqu'au dernier jour de sa mort, elle parût plus considerable par les redoublemens qui survenoient, l'un le matin plus leger, l'autre sur les quatre heures de l'apres disner qui commencoit par une toux assez violente c'est ce qui a duré jusqu'au dernier jour La nouvelle de cette maladie ayant este sceüe à Paris Monseigneur le Mareschal de Villeroy par son zele très vif et très fidelle par la Reyne me fit l'honneur de m'ecrire pour offrir à la Reyne les medecins de la cour qu'elle souhaiteroit Sa Majesté demanda Monsieur Dodart, aujourd huy premier medicin du roy et Monsieur Boudin Ce sont les deux qui la traittement dans sa grande maladie dernière Ces medecins sont venus tous les jours depuis mardy jusqu'au vendredy, veille de la mort D'abort ils ne trouverent rien de mortel dans cette fievre ils ordonnerent une second saignée, la premiere ayant esté faite des le lundy par l'ordre de Mr le chevalier Garven Cette suite de redoublements et de toux les a embarrassés mais ils n'en ont pas paru trop alarmes Le mercredy et jeudy se passerent de mesme facon et mesme la nuit du jeudy au vendredy fut si bonne qu'on commenca à mieux esperer et mesmes on ordonna une medicine pour le lendemain samedy Pendant tout le temps la j'ay rendu mes assiduités à la reyne la messe tous les jours et les prieres ont esté dites dans sa chambre Des le jeudy la reyne demanda a se confessor Les medicins me prierent de l'en detourner de peur que la preparation à la confession ne donnat quelque agitation, qui lut pû troubler le bon estat qui sembloit s'establir Je priay la reyne de differer sa confession Le lendemain vendredy elle m'en parla encore avec quelque inquietude de mourir disoit elle sans confession Ce qui me determina à consentir à sa demande fut une toux très forte et un redoublement tres violent qui la prit vers les cinq heures du vendredy peu apres que les medecins furent partis avec esperance de la trouver mieux le lendemain disant pourtant qu'ils trouvoient la fievre bien ardente Je traitty alors avec la reyne l'affaire de la confession sur l'empressement qu'elle m'avoit marqué Pour la delivrer de tout inquietude je la priay de prendre tranquillement tout cette preparation qu'il falloit faire tranquillement sans manquer à prendre tous les soulagemens qui devoient l'interrompre Ainsi fut il fait. La reyne me fit sa confession avec les sentimens ordinaires de sa grande piété et de son vif amour pour Dieu dans une grande paix Quelque heure apres ou trouva que la reyne s'afoiblissoit et que la violence du mal s'augmentoit. Je pris avis de Mr Garven s'il jugeoit qu'il fut temps de luy faire recevoir les derniers sacremens Il en fut d'avis je n'eus nulle peine à en informer la reyne qui n'en fut pas plus emue que si on luy avoit dit d'aller entendre la messe dans les temps de sa santé Je fis avertir Monsieur le prieur curé de la parroisse pendant que j'estois attaché à preparer la reyne à la reception des divins sacremens L'extreme onction luy fait premierement donnés par M le Curé et en suite le st viatique Avant que de la recevoir elle fit demander pardon à toute l'assistante des peines qu'elle avoit pu faire a qui que ce soit, donc monsieur le curé fit le recit public. Depuis ce temps la, ou tout fut achievé à onze heures et demie du vendredy jusqu'au lendemain sept heures et demie du samedy la reyne ne vouloit plus s'entretenir qu'avec Dieu Elle demanda les prieres des agonisans sur les deux heures apres minuit. Comme on les faisoit au pieds de son lit elle ordonna qu'on s'aprochat pour les mieux entendre et y repondre Les prieres ont esté faits deux fois par messieurs les aumosniers de la reyne, auquels je rependois Mon occupation fut depuis onze heures et demie du soir vendredy jusqu'à sept heures et demie samedy de me tenir auprès de la reyne, et de me presenter de temps en temps à elle pour luy fournir des sentimens de pieté Certainement elle n'en avoit pas besoin Car Dieu luy inspiroit luy mesme les plus dévots sentimens Elle voulut avoir le crucifix entre ses mains et sous ses yeux et tout cela partagé entre les prieres que l'on faisoit aupres d'elle, et les sentimens qu'elle prenoit ou d'elle mesme ou de ce que je luy suggerois Tout cela s'est passé avec toute la presence de son esprit pendant que le corps se détruisoit par l'oppression de la poitrine ou tout le mal a abouti et par l'inflammation qui s'y est faite, mais avec quelle douce patience a elle tout souffert pendant la durée de huit heures apres les sacremens receus ayant toujours non seulement l'esprit mais la parole libre jusques à un quart d'heure avant sa mort, et mesmes dans ce quart d'heure elle me donna des signes qu'elle entendoit tout ce qui je luy disois sans pouvoir former des paroles pour y repondre. Ainsi ainsi cette sainte reyne s'est elle endormie au Seigneur auquel du samedy matin 7e may 1718 J'avois oublie qu'a quatre heures du matin elle demanda que la messe fut dite dans sa chambre à quoy elle s'unit par toute l'affection de son cœur 2nd Article: Voicy ce qui vous regarde personnellement dans les sentimens de la reyne vous aves connu son cœur tendrement maternel qui s'est toujours conserve tel jusqu'a sa mort, vous n'ignores pas aussi les peines qu'elle a ressenties sur les derniers ordres qu'elle avoit receus de votre Majeste Très persuadée de toute vostre affection elle m'a ordonne de vous mander que tout ce qui luy estoit venu de vostre part, quoyque contraire à ses pensées et à ses inclinations n'avoit fait aucune impression contraire à son affection et qu'elle ne vous scavoit aucun mauvais grè mais qu'elle vous prioit de luy pardonner toutes les peines qu'elle auroit pu vous faire par les petites contestations sur quoy elle m'a ordonné en termes exprès de vous dire de sa part les choses les plus tendres et de vous asseurer qu'esperant la misericorde de Dieu elle prieroit le Seigneur dans le ciel pour le succes de vos affaires presentes, j'ay cru mesmes avoir entendu qu'elle a nomme particulierement l'affaire des Suedois D'ailleurs en recevant le st viatique, ayante demandé qu'on priat pour elle, elle ajouta pour le roi mon fils âfin qu'il perde mille vies plutost que de souffrir la moindre alteration de sa loy ce qui fut repeté tout haut par M le curé lors que de la part de la reyne il dit, que sa Majesté demandoit pardon de toutes les peines qu'elle avoit pu faire à qui que ce soit. En suite elle s'est fait aporter un petit crucifix qu'elle a mis entre les mains de madame de Molza avec ordre de vous l'envoyer de sa part, ce qu'elle luy a encore reitere une autrefois, âfin que son ordre sur ce sujet sois fidellement executé "

Sir Hugh Paterson to the Duke of Mar —1718, May 20 Rotterdam.— We have now the afflicting news confirmed of the good Queen's death By a letter I have seen from one that was present during her sickness till her death I find that the physicians that attended her are much blamed for their conduct, and since I mention this, I must tell you that many of the King's friends both here and at home seem concerned that he has not a more skilled physician and of a better character about his person than the one they hear is at present with him I remember very well when the Princess died that some of those then present complained very much in their letters to England, of the conduct of the physicians that attended her and that he that's now with the King was particularly blamed about it. I hope he shall have very little occasion for the advice of any of them but, should it please God to make it otherwise, it would be no small grief and uneasiness to his friends to think he should want the attendance of a prudent skilled physician which I must take the liberty of saying Dr Macgie is far from being thought. I have often been pressed by many to represent this, which I have omitted doing till now therefore, if it's thought officious I hope it will be excused since it proceeds from no other motive than a true zeal for the King's welfare "

(*To be concluded.*)

DRUGGING BY A DENTIST

To the Editor of THE LANCET

SIR —I was last night called to see a patient who gave me the following account He had that day been to see a dentist who was treating him for a carious tooth, to which the dentist applied a dressing and gave him a bottle containing 42 pills, each of which, according to the label on the bottle, contained morph sulph gr ¼ He was directed to take one to three till relieved of pain Fortunately, after taking two he felt ill and sent for me

I am, Sir, yours faithfully,
W GILCHRIST BURNIE

Bradford April 3rd 1917

THE MANGOLD WURZEL

THE Food Controller has just issued recipes for cooking mangold wurzels In this connexion the following paragraph from The Dictionary of the Farm,' by the Rev W L Rham, vicar of Winkfield, Berkshire (1773-1843), a book which was very popular in its time, is of interest to medical men —

> The common field beet for cattle which has long been known in Germany was introduced into England at the latter end of the last century and its introduction is generally attributed to the late Dr Lettsom a physician of reputation and a member of the Society of Friends The German name is mangold wurzel" or mangold" root but it is commonly pronounced "mangel wurzel which means

scarcity root and by a strange translation it is called in French *racine d'abondance*, or root of plenty as well as *racine de disette* or root of scarcity The name of field-beet is much more appropriate

Mr Rham also supplies much further information concerning the mangold and its cultivation In the Dictionary of National Biography it is stated that John Coakley Lettsom translated a pamphlet on the subject from the French of Abbé de Commerell in 1787, grew the mangold himself, and imported a large quantity which he distributed to farmers and others in this country as well as in Europe, America, and the West Indies

The following are three recipes for cooking the mangold wurzel issued by the Food Controller —

Recipe 1—Ingredients 1 lb mangold wurzel ¼ lb vegetable butter or dripping 2 small onions pepper and salt.

Cook the mangold wurzel in the butter for about 20 minutes or until tender Then add the onion (which has been previously chopped) and pepper and salt Drain for a moment before serving on cooked lentils buttered rice, or cheese sauce

Recipe 2—Ingredients 1 lb mangold wurzel 2 oz. vegetable butter or dripping 2 tablespoonfuls of stock (vegetable or meat) a little pepper and salt

Cut the mangold wurzel into small dice Dust them in whole meal flour Place in saucepan together with the butter and stock and let simmer till tender but care must be taken that the mixture does not boil Serve as a vegetable

Recipe 3—Ingredients 1 lb mangold wurzel

Cut into dice and cook as for No 1 Drain and then dip into a batter made from the following: 1 egg ¼ lb flour 2 oz bread crumbs sufficient milk to make a nice frying batter Fry in vegetable butter and other cooking butter or dripping

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot undertake to return MSS not used.

Offices 423, STRAND, LONDON, W C 2

MANAGER'S NOTICES.

SURGEON TO ST THOMAS'S HOSPITAL CONSULTING SURGEON BRITISH EXPEDITIONARY FORCE.

LECTURE II[1]

Delivered on March 22nd 1917

THE POSSIBILITY OF SPONTANEOUS RECOVERY AFTER THE PERFORATION OF HOLLOW VISCERA

MR PRESIDENT AND GENTLEMEN,—It is quite true that people do recover after wounds of the hollow viscera, but the number is very few Those who recover may be said to be the exceptions that prove the rule

1. We have instances of late-formed fæcal fistula which may be due to sloughing of the bowel wall or to actual perforation There have been fairly frequent instances of recovery after wounds of the colon as has been insisted on by Makins, who by the way, attributes such a favourable result to the intense local reaction produced by the contents of the colon

2. Actual proof of the healing of the stomach was seen in a case in which a fragment of a mantle of a bullet perforated the liver on the anterior surface penetrated its thickness, and wounded the stomach. The officer lived some days and at the post-mortem one found evidence of a wound of the stomach which was closed, partly by its own reaction and partly by the application of the left lobe of the liver The post-mortem was made by Captain J S Dunn. I have no doubt that if this officer had not succumbed to his other injuries the wound of the stomach would at the worst have led to a localised abscess

3 For the history of this remarkable case I am indebted to Surgeon General Bowlby and Captain Bell

A soldier was shot from side to side through the body at the battle of Loos He was not operated on and recovered As far as I know, there was nothing special about his convalescence He was again shot in the abdomen in the battle of the Somme and was operated upon When the abdomen was opened several perforations of the small intestines were found in the neighbourhood of a mass of adhesions The wounded and adherent segments were excised and the man made a good recovery On slitting up the adherent coils an entero-enterostomy was found between two adjacent loops in addition there were several small herniated diverticula of the mucous membrane obviously pointing to closure of the previous penetrations

This case is of interest because the process of healing corresponds to that which Captain H. Drummond has shown to be the case when the intestines of rabbits are perforated and put back without suture The herniated mucous membrane remains herniated and gradually becomes covered with a layer of lymph which slowly organises and seals the hole, the herniated mucous membrane still forms a diverticulum

RUPTURE OF VISCERA WITHOUT PENETRATION OF THE ABDOMINAL CAVITY

1 As in civil life one meets with a fair number of abdominal injuries caused by horse kicks, by falling in of dug-outs, by burial of men by shell explosions and by blows of fragments of wood which are hurled about, they present nothing out of the common and the injuries seen are the same as in civil life Captain J B Haycraft had one case which may be mentioned in which the post-mortem examination on a man who died after burial by shell explosion showed numerous contusions of the small intestine without rupture

2. Similar injuries are caused by large shell fragments usually shell caps and several cases of the latter injury have been seen in which rupture of the intestine was accompanied by extensive contusions Some years ago Makins wrote a paper on this subject and he came to the conclusion that such injuries are caused by the bowel being caught between the unyielding posterior abdominal wall and the on coming object This supposition, I think, is strengthened by the association of bruises along with perforations in the case already quoted

3 *Rupture of solid organs by indirect violence of a passing projectile* —Such injuries are by no means uncommon. Here is a picture of a kidney in which many cracks in the capsule were produced by shell fragments which did not themselves touch the organ. I have also seen two cases of ruptured spleen, in each case the left lower chest was hit and the ribs broken in both cases In one the diaphragm was intact but on opening the peritoneum much blood escaped and there was an extensive tear in the spleen In another case the diaphragm was ruptured over a small area, the blow being a glancing one There was a corresponding wound on the outer surface of the spleen, and from this wound there ran in all directions radiating fissures in the capsule, showing that the spleen had been burst by the indirect blow it had received

4 *Cases in which the viscera are damaged by indriven bone fragments* —(*a*) There are many cases of injury to the liver and spleen by the driving in of fractured ribs There is nothing particular in these

(*b*) The cæcum and the ascending and descending colon and also the small gut in the pelvis are all apt to be injured by small bony spicules driven in through the peritoneum Although the projectile itself does not penetrate this membrane, it is important to remember this possibility because when such wounds are explored it is most probable that the small holes caused by the bony fragments would be overlooked and the peritoneum assumed inviolate

5 *Rupture of hollow organs by indirect violence* —There seem to be two classes (*a*) Rupture of the intestine by a bullet without penetration, and (*b*) rupture of a viscus out of the track of a perforating bullet Cases have been reported by Owen Richards, John Fraser, J W Dew, and others

(*a*) The first case was that of a man whose recti were divided almost completely by bullet The wound was explored and the posterior rectus sheath found intact As there were no symptoms the abdomen was not opened the man died At the post-mortem examination a careful search failed to show any rupture of the peritoneum There were three holes in the small intestine which lay immediately under the wound in the abdominal wall showing the gut had not moved although more than 24 hours had elapsed since the receipt of the injury

Fraser's case was that of a man wounded by a piece of shell in the right iliac fossa and in which the cæcum was found bruised and a small hole in the mesenteric border of the ileum

In Dew s case the projectile had cut all the abdominal wall through save the peritoneum through which the cæcum could be seen As there were no symptoms the abdomen was not opened but the man died from a ruptured ileum

(*b*) Fraser has also published another case in which the bullet penetrated the abdomen just below the umbilicus. There were no symptoms at first, but when they arose later on cœliotomy showed a ruptured bladder The bladder was apparently out of the direct line of the projectile

These ruptures may be caused apparently in three possible ways For instance, (1) when an object such as the abdomen and its contents made up of layers of varying toughness, is sharply hit more friable layers underneath may come away, while the more resisting overlying layers remained intact (2) This may be termed the "paper bag' theory, the intestine being ruptured by a smart blow in a similar way to that in which an inflated paper bag is burst on being hit. I do not know that there is any proof that this happens but it is rather a seductive theory (3) There is another possibility which must not be lost sight of. A man when he is hit may fall to the ground or against some object and the ruptured intestine be due to the blow thus produced and not to the actual missile which was the indirect cause of the fall

MECHANISM OF WOUND PRODUCTION AFTER PENETRATION

The multiplicity of wounds of the small intestine has raised some doubt as to their method of production, especially in the case of bullets where types of wound widely different in nature are seen The question arises, Can a bullet pursuing a straight course cause these injuries or must we invoke a rotation of the bullet or a bursting effect ?

If a bullet is rotating quickly on a transverse axis it could easily produce complete division of the gut but if it is radiating quickly enough to produce such injuries it is hard to see how it could at the same time produce small perforations Some support is given to the rotation theory by the retention of many bullets, as one knows that their flight is unstable at the end If the rotation theory is correct, one ought to have some evidence of this rotation at the entrance and exit holes As a matter of fact, it is impossible to establish any relations between the size of the entrance and exit wounds in the skin and the amount of damage done to the intestine As to the possibility of a bursting effect it is impossible, I think, to make any definite statement on the subject. All that one can say is that when great vessels are hit by bullets nothing has ever been seen in the nature of a lesion which suggested the presence of the so-called hydrostatic phenomena

---

[1] Lecture I was published in THE LANCET of April 14th 1917

I am rather inclined to think myself that these different types of wound are caused by the varying state of distension of the small gut As is well known one meets with lengths of the small intestine alternately distended with air and collapsed If the bullet strikes a distended portion it will perforate it or cut a hole in it If it strikes a portion which is collapsed, the intestine is so small that the diameter of the bullet is such that it could divide both coats

DIAGNOSIS OF INTRAPERITONEAL DAMAGE

This is determined in three ways (*a*) By inspection, (*b*) by experience, (*c*) by symptoms With all possible care and an extensive experience and a full appreciation of the numerous fallacies, it is frequently difficult to make sure that the wound is penetrating If it is difficult when there is an entrance and exit wound it is still more so when there is only one wound It may be that shock hæmorrhage rigidity, or rapid pulse will be present, but in some cases which are received early there will be no such guides The wound of a hollow viscus may in itself have no symptoms if it is not extensive enough to produce shock, it is usually hæmorrhage or peritonitis which gives the danger signal As there is a distinct relation between the interval since the receipt of the wound and the operation it is important to be able to determine the probability of penetration

(*a*) *By Inspection*

Antero-posterior wounds are the easiest to judge The only point to be remembered is the thickness of the flank muscles Below the transpyloric plane a wound with the entrance on one side of the middle line and an exit exterior to the lateral body line of the same side is very often non penetrating, or one that has just opened the peritoneum Above the transpyloric line such a wound, owing to the rounded form of the thorax, is almost certain to be penetrating The bullet which passes in and out between the semilunar lines probably does not open the abdomen, while that wound that passes in and out outside these lines probably does In the longitudinal direction a bullet which enters near the costal margin and emerges above the groin will most likely traverse the abdomen Where it is a question of single wounds there is really nothing except the symptoms to guide one as it is usually impossible to tell the direction of the projectile A great deal of help is afforded by an X ray apparatus in such cases

One case may be quoted as showing the difficulty of judging where a missile has gone

A man was shot beside the umbilicus The shape of the wound suggested a bullet, the area was a dangerous one, so it was determined to explore the abdomen As the wound was in a convenient situation the exploratory incision was made through it It was then found that the rectus muscle was torn the length of the incision This was enlarged downwards to the pubes the muscle being much torn down to the bone, but the sheath and peritoneum were intact The bullet had passed down behind the pubes and, as there were no symptoms nothing further was done, and the case, after an interval of several days, was sent to the base doing well

(*b*) *By Experience*

This has shown that one has to be very careful in making a negative diagnosis and it has also shown the wisdom of operation in doubtful cases Bomb wounds require some notice under this heading The fragments into which a bomb is broken on explosion are often very small but so high is their velocity that they have very great power of penetration The wounds are often so small and insignificant that it sometimes takes some strength of mind to explore the abdomen, although the symptoms point to the possibility of visceral involvement The number of these wounds makes individual exploration impossible, and the only way of settling the matter is to explore the abdomen by a well placed incision, irrespective of the situation of the wounds

(*c*) *By Symptoms*

These may be enumerated as follows —Appearance, pulse, vomiting, hæmorrhage, rigidity, pain, tenderness, shock, and subjective sensations

Appearance —Usually a man hit in the abdomen looks ill He is shocked and cold, often in spite of blankets and hot bottles, with which he has been surrounded in the ambulance Sometimes he is apathetic and quiet, sometimes restless—sometimes from pain—sometimes from distress He may be blanched or of a fair colour, even normal in appearance Before rapid evacuation was the rule I was struck by the fallaciously good facial expression of some of these cases, and it was often that one experienced a shock on taking up such a man's hand to find it cold and clammy and the pulse running or even not palpable Such cases invariably die, and operation only hastens their end

Pulse —A rapid pulse, a pulse that does not fall, or a rising pulse is an indication for operation A slow pulse is not necessarily a contra indication unless the wound is in a non dangerous area such as the liver I have seen a man with a pulse of 60, with four holes in his small intestines, four hours after receipt of the injury A rapid pulse is caused by loss of blood, and later on by peritonitis and sepsis It does not seem to have any very definite connexion with the number of lesions of the intestine The pulse often falls with rest and infusion, and it often happens that a falling pulse is more an indication of the possibility of operation than a contra indication to operative measures A rising pulse is an indication for operation

From Table V one can see the general average of the pulse of a man wounded in the abdomen A pulse of 100 is very frequent and, on the whole gives a good prognosis A pulse of 110 seems to be a critical one, for the mortality after this rapidly mounts

TABLE IV

Pulse up to—	-60		-70		-80		-90		-100		-110		-120		-130		-140	
	B	D	B	D	B	D	B	D	B	D	B	D	B	D	B	D	B	D
	1	1	3	0	8	6	14	10	49	23	12	19	21	46	5	23	7	36

B = To base D = Died.

Mention may be made here of unexpected results which some pulse rates show A man with a pulse of 160 with a wound in the liver went to the base without operation Another pulseless man recovered after his bladder and small intestine had been sutured A man with a pulse of 60 died from the effects of hæmorrhage, although the bleeding was stopped by operation A fourth man with a pulse of 90 died from gas gangrene in the abdominal wall, a fifth with a pulse of 80 died from peritonitis on the third day, and another with a pulse of 160 recovered, the reason of the rapidity being extraperitoneal hæmatoma of the bladder, which was drained From these instances it can be seen that, although the pulse is a very good indication, there are many surprises for the surgeon

Vomiting —Wounds of the stomach nearly always lead to vomiting and very often to hæmatemesis, but vomiting is also met with in all kinds of abdominal injury, and beyond the fact that its absence shows that the stomach is most probably not involved it has no special significance

Hæmorrhage —This will be dealt with under wounds of different organs, and it is sufficient to say here that with the exception of blanching and a rapid pulse both of which may be produced by other causes, the classical signs, such as restlessness, blindness, or air hunger, are usually absent When present it gives the ordinary physical signs but, as is well known, these are not very helpful, as to produce them the amount of blood may have to be very great

Rigidity —A very constant but varying symptom when the cases arrive It is seen in low thoracic injuries, wounds of the abdominal wall and in contusions of the abdomen and with true visceral injuries

(*a*) The rigidity produced in the abdomen by low thoracic injuries is well known, and it renders diagnosis very difficult, especially in those cases where from a study of the track the bullet may or may not have entered the abdomen

One such case I well remember in which a man, hit in the lower right axillary region, presented a universal rigidity of the abdominal wall accompanied by considerable pain His condition otherwise was not bad It was determined to watch him, and he was put to bed and kept quiet for three hours At the end of that time the rigidity had become board like There was considerable increase in his pain and his pulse rate was slightly accelerated An abdominal exploration showed that after all the abdomen was uninvolved, and that the only possible injury was a wound of the liver on its extraperitoneal surface Curiously enough this man died a week later from tetanus

I do not know that there is any royal road to diagnosis between a thoracic and abdominal wound , every case must be judged on its merits Captain B C Maybury has an idea that superficial abdominal tenderness is rather a feature of thoracic wounds

(*b*) In the case of abdominal wall wounds the rigidity is apt to be local and as a rule, it does not give rise to very much confusion. Contusions of the abdomen do present considerable difficulty, and in cases which have recovered without operation I have seen rigidity, an extremely rapid pulse, and pallor all combined. Wounds of the pelvic floor, even when not penetrating, will produce a reflex hardness of the anterior wall, and the same may be said for some wounds of the upper thigh.

(*c*) *Visceral injury* —Injuries both of the solid and hollow viscera are accompanied by rigidity This rigidity seems to be brought about in three ways (1) it is a reflex protective measure after the receipt of any wound , (2) it is also brought about by irritation of the peritoneum either by blood or infection , (3) it is largely independent of the amount of peritoneal infection and occurs in extreme form without any naked-eye appearances of inflammation. Under such conditions it is generally accompanied by very great pain

Rigidity often occurs when there is blood in the abdomen the source of which is only a wound of the mesentery or omentum It is not as a rule very marked in these cases and tends to subside with time in distinction to that due to peritonitis, which is progressive One occasionally sees a somewhat rigid and tumid condition of the abdomen in cases arriving late Such a condition is, according to my experience, usually only a sign of hæmorrhage which has been arrested, and I always advise the leaving alone of such cases

Considered clinically, (1) rigidity may be slight, and this generally or local (2) It may be confined to one part and if this spreads it generally means an intestinal lesion. (3) Alternating rigidity During examination the abdomen is sometimes soft and sometimes hard. This is a very puzzling condition and its indication is not very clear , it is sometimes accompanied by extensive injuries (4) Apprehensive rigidity if one may use the term Here although the abdomen looks soft and moves on respiration, it at once hardens when the hand approaches to palpate. As a rule it is accompanied by no serious injury (5) Board like rigidity is most puzzling when accompanied by a slow pulse. If there is extreme pain it nearly always means that there is a wound of the intestine (6) Complete absence of rigidity, this when accompanied with obvious penetration of the abdomen, has often a grave significance, as has been pointed out by Taylor and Meyer Such cases often quickly end fatally It may be here stated that morphia in moderate doses seems to have very little effect on the state of the abdominal wall

The spinal abdomen —One has to be on one's guard not to be misled by the slightly rigid and tumid abdomen which is met with in cases of spinal injury, and especially when such injuries are accompanied by vomiting This state of the abdomen is sometimes caused by a distended bladder, but it may be present without it

Tenderness —This phenomenon has very much the same value as the tenderness met with in penetration of the intestine due to disease *Pain* is nearly always present in some form or another, but it varies from almost uncontrollable agony to nothing more than discomfort There does not seem to be any particular relation between the amount of pain and the amount of injury

Shock

This can be considered under two heads (1) subjective sensations , (2) shock proper

1 *Subjective sensations* —The sensations of a man shot in the abdomen vary in a remarkable degree As can be well imagined the size of the projectile must have a considerable influence The shell fuse cap produces much the same effect as a violent blow from the heels of a horse, although there may be no open wound, and the subsequent course proves that there is no visceral injury A somewhat similar effect may be produced when a portion of the abdominal wall is torn away but as the blow is a more or less glancing one in such conditions the amount of "knock out" effect is often surprisingly little Men have walked considerable distances with such wounds, their intestines supported by a bandage To quote a case —

A man had his abdominal wall ripped open by a bullet just as we were being compelled to evacuate a trench He was bandaged up with a shell dressing, and insisted on walking to a trench in the rear, where he lay on the fire-step for some time until things became quiet and he was able to be taken away to the ambulance He made a complete recovery

Sometimes a man, though he knows that he has been hit in the abdomen is quite unconscious that his intestine is prolapsed, although a considerable amount may be outside his body To quote a case —

A man was hit just above the pubes , he experienced very little inconvenience When the first dressing was applied some of the small gut lay on the belly wall This was covered up with a dressing and the man taken straight to an advanced abdominal hospital When he arrived there he was in good condition and in no pain Six or seven feet of small intestine perforated in places lay under the dressing He made a complete recovery after operation

When the missile is a small one and penetrates and wounds the intestine there may be very little pain or disturbance

One man, hit in the iliac region, in whom a subsequent operation proved intestinal injury, was quite unconscious that he had received a severe wound. He thought that he had been hit in the leg, the bullet having disturbed some of the lumbar nerves

Another man, a bearer in the R.A.M C , who had been wounded in the abdomen and, as subsequent operation proved, in the intestine, was brought on a stretcher to an advanced dressing station, but seeing there were many wounded to be attended to he got up off his stretcher and lent a hand

Another case may be quoted as showing how little disturbance a wound in the intestine may produce It was one of the cases I saw early in the war, and which confirmed my opinion that the expectant treatment was wrong This officer had a side-to-side penetrating wound of the abdomen When I saw him at a clearing station about six hours after receipt of the wound he was in good condition, free from pain, cheerful and smoking a cigarette He was unoperated, he was dead of peritonitis in 24 hours Post mortem he had a single hole in his intestine

On the other hand, a man shot in the abdomen by a bullet or some of the smaller projectiles may experience a tremendous blow which may knock him out Now this sensation of a tremendous blow is experienced even when small missiles hit the limbs It is curious to remember that the blow or kick sensation is experienced by those who rupture muscle fibres while playing games It is therefore legitimate to imagine that the sensations of a violent blow have nothing to do with an injury to the solar plexus

Pain of an intense character is sometimes experienced immediately after the receipt of the wound, and it accompanies wounds both of the upper and lower abdomen In the latter case it was specially connected with penetrating buttock wounds The suddenness of the pain in these cases recalls that seen in perforation of gastric ulcer or appendix This similarity suggests that the cause of pain is connected with an irritation of the peritoneum by the bowel contents although the escape of such matter may not be perceptible at the operation Some people hold that the contents of the jejunum are more likely to cause pain than those of the ileum

The following case is an example of intense sudden pain and a board like rigidity which so often accompanies it It should be noticed that his pulse was only 60

L C was wounded in the back by rifle grenade, he was admitted within four hours of the wound He was pale and suffering intense pain in spite of morphia His abdomen was like a board His distress might have been increased by the fact that, being hit in the abdomen, he was quite sure he had got to die He was taken to the theatre and when examined the only wound found was a small puncture on the outer side of the erector spinæ Operation disclosed one abrasion and three perforations of the jejunum There was no visible escape of contents Recovery was uninterrupted The fragment that caused the injury was no larger than a large safety match head in bulk and so small that its weight could scarcely be appreciated by the hand

2 *Shock proper* —Everyone understands in a general way what is meant by shock and has in his mind a picture of a patient in such a state When asked to define what he really means by shock he will very likely be unable to answer this question As regards the abdomen, a state of clinical shock is produced in various ways—by a violent blow, by multiple intraperitoneal abdominal injuries, by hæmorrhage, by sepsis, which seems to be of the nature of poison shock, and by pain

If a man is hit by a large projectile the blow will produce shock, just as any other blow will do The man is winded or knocked out. Again, extensive injuries of the abdominal wall with exposure of the intestines will cause shock This is also true of multiple injuries of the abdominal viscera, and there can be no doubt that the gravity of any case does rapidly mount with the number of lesions in the viscera and the number of viscera injured Apart from these generalisations, it is very hard to make any definite statement as to the relation between the amount of shock present on the one hand and the organs injured and the amount of individual damage on the other

Some idea of what a man's state may be after a wound in the abdomen has been given when speaking of a man's subjective sensations, and it can be seen from that that immediately after the receipt of the wound that proves fatal a man may for a considerable time be able to pursue what he was doing I might quote here another case as illustrating this

A flying man, well over the German lines, was hit with a high-explosive shell, it entered somewhere behind the anterior superior spine, traversed the abdomen, caused two holes in the small intestine, and then lodged in the areolar tissue behind the pubes The man brought his machine back, made a good landing, and was brought into the casualty clearing station near by in really first-class condition He was operated on, the wounds in the intestines sewn up, and he died within 48 hours of acute sepsis produced from the retroperitoneal tissue

There is considerable difficulty in ascertaining the connexion between the actual damage done and the amount of shock Regimental medical officers who see cases early can form no idea, apart from the loss of abdominal wall or protrusion of viscera, what the extent of the abdominal injury is, and by the time the cases come to operation there are the added factors of loss of blood and sepsis The amount of shock seems to be largely due to the loss of blood, and if one could only find some easy method of supplying this fluid it is possible that our results might be very greatly improved The transfusion of blood although it is a comparatively simple process, is more or less cumbrous and can only be employed when conditions are quiet and when a donor is available

A word may here be said about the effect of lesions on individual organs It has been stated before that in the case of the liver one meets with some cases of shock which do not seem to be explained by the amount of damage or the amount of blood lost Wounds of the spleen, apart from hæmorrhage, even though severe, do not cause much collapse The same can be said of the kidney, and this is perhaps rather remarkable when one remembers the effect of the kidney punch in boxing In some instances there is great shock and a pulse of 140, followed by recovery without operation

The stripping up of the retroperitoneal tissue by blood seems to cause shock out of proportion to the amount of blood lost The great pain of a small injury will often produce pallor and collapse and cold extremities, while the pulse is quiet

There is tremendous scope for the investigation of this subject, and work is being done, notably by Captain Geoffrey Marshall. It is not a question of preventing shock so much as of curing it, for it is impossible to apply the ordinary anti shock procedure to a man before he is wounded The clinical shock produced by sepsis is often very marked and may cause death in a comparatively few hours This, again is well seen in cases that are dying of gas gangrene of the limbs

Care of the Patient before Operation

In transit to hospital —First of all, a man, wounded in the abdomen, is more comfortable if he can be put in such a position that his abdominal muscles are relaxed He should be covered up and kept as warm as possible and saved all the jolting possible, though, from the nature of things, this cannot be done very effectively He should be given a reasonable dose of morphia—this will relieve his pain and mental anxiety It is well to say a word here about the administration of morphia After the first injection has been given a reasonable time should elapse before another dose is administered This warning is necessary because patients have arrived at the casualty clearing station very profoundly under the influence of the drug Not infrequently, too the patient has been dosed either by himself or by his companions without the knowledge of the medical officer

The withholding of water —There is no reason why water should not be given in reasonable amounts, its withholding causes great distress to the patient, who very likely is already suffering from a lack of fluid in his body

In hospital —When a patient arrives at an operating hospital the question of immediate operation has to be considered On the whole, it is better to put the man to bed and watch his condition for a little than immediately to subject him to operation It is quite true that hæmorrhage is the great danger, but, still, my experience has led me to think that on the whole a little rest does more good than harm The interval is used to improve the man's condition.

First and foremost as a remedial measure is the warming of the patient This is by far the best treatment of shock that I know and far transcends in its importance the ministration of stimulants of whatever nature, either by the mouth or hypodermically The radiant electric bath covering the whole body is by far the most efficient method of applying heat, and should be used wherever an electric current is available

Fluid can be introduced into the system by the mouth, subcutaneously or intravenously It just depends upon the state of the patient and his capabilities of reception I would only say that the intravenous method is by far the best and surest and is the only way of any practical use if time is an object The fashionable method of subcutaneous saline is practically valueless in a shocked man Pituitrine is favoured by some people

The actual moment for performing the operation must be left to the individual judgment of the operator If the man does not respond at all, the question must be decided whether to operate at once or whether it is worth operating at all Sometimes even as much as six or eight hours' rest will produce such improvement that an operation is possible where at first the case seemed hopeless

General Lines of Treatment

Cumulative experience shows the wisdom of operation in most cases, and it is now mostly a question of excluding cases on which it is best not to operate It can be frankly admitted that this line of treatment involves operating on certain cases which would have got well without operation It also involves operating on a certain number of cases, such as those in which there is bleeding without visceral injury, which might have got well without operation, but there is no way of telling if the hæmorrhage has stopped except by looking

In a certain number of cases the intraperitoneal hæmorrhage, although the hæmorrhage has ceased and is not immediately fatal, not infrequently leads to intra abdominal abscess later on On the whole it may be said that a policy of "Look and see" is better than one of "Wait and see" It may be useful to enumerate those cases which are best left alone

1 Cases in very bad condition Now there are of course many cases which no surgeon would feel himself justified in operating on, but there are many border line cases which some surgeons would leave and some to whom the surgeon would feel constrained to give the chance of operation. Here the personal equation comes in, and whether he operates or not must be left to the surgeon to decide He should, however, remember the indications of Table IV (Pulse rates) It need only be added here that the bolder surgeon will most probably get a worse operative mortality

2. Cases shot high up in the abdomen and in the liver area on the whole do very well if left alone, so long as there are no symptoms of hæmorrhage , in fact, hæmorrhage is the only reason for operating on liver cases It is, of course, true that a certain number of these succumb to sepsis at the base but their number is not sufficiently great to warrant early interference on that account

3 High abdomino thoracic wounds on the left side The type of wound more especially referred to is that which enters somewhere near the mid line behind and emerges somewhere towards the posterior part of the axilla about the level of the sixth to eighth rib These wounds are sometimes accompanied by symptoms suggesting stomach involvement but on the whole they do not do badly, and operative interference does not afford very much help, as wounds high up in the cardia, or near the œsophagus, are almost impossible to close , or, if they can be reached, involve such disturbances as to be likely to lead to a fatal result

4 Cases arriving late. I am inclined to put down 24 hours as a usual limit within which a primary operation is likely to be successful Hæmorrhage by this time has ceased and operation is only likely to spread infection if the bowel has been perforated and to hasten the end There are some cases in which operation may be thought advisable—namely, those with a fair pulse but with vomiting, and the operation being performed with an idea of getting over the "obstruction" by short-circuiting or an enterostomy The operations that I have seen performed for this reason have nearly all been fatal

The so-called Murphy operation—that of simple suprapubic drainage—is, I believe, an absolutely useless disturbance, and has, I see, been abandoned by the French, with whom it was an official proceeding in the early days

The operation table —The Trendelenburg position should be ready for use Most important is the provision of some heating arrangement on which the patient can lie

246

INCISION

1 *Its site* —This must be planned rather with a view of dealing with the probable nature of the injury than with any reference to the wounds With an in and out wound we know the course of the projectile and can form a fair estimate of the organs likely to be involved With a single wound this is practically impossible, and it is here that an X ray apparatus is so valuable, as it enables us to make the abdominal incision in the best possible place.

To give an instance of the value of an X ray apparatus suppose there is a single entry wound near the middle of the abdomen Without an X ray apparatus the only thing is to open the abdomen in the middle line and find out the course of the bullet, and this involves an exploration of the whole abdomen , and in the end it may be found that the only viscus injured is the colon at its peritoneal reflection The exploratory procedure will have exposed the whole abdomen to the danger of contamination On the other hand, an X ray picture would have located the bullet in the loin and shown at once that a horizontal exploratory wound would have met all the circumstances of the case and possibly saved a life

A paramedian incision is the standard method of opening the abdomen and it should be used in all cases unless there is some distinct indication to the contrary It is always better to prolong it than to make lateral right-angle extensions The length should be 6 to 8 inches probably the longer is the better, as free access means a very great increase in celerity

In some antero posterior wounds towards the lateral line of the body a rectus sheath incision has something to recommend it , the colon can be more easily reached and the field of operation limited It is not, however, a good incision to close and it divides many nerves Both the hepatic and splenic flexures can be reached by the rectus sheath incision the hepatic with a good deal more ease however

In those cases where the missile has perforated through the body from near the mid line to the loin whether this direction is shown by an entrance or an exit wound, or by the aid of a skiagram the transverse incision either horizontal or parallel to the upper or lower abdominal limits, has much to recommend it If more room is required it can be obtained by cutting the anterior rectus sheath but leaving the rectus muscle intact Such an incision allows free access to the hepatic and splenic flexures, to the vertical colons, to both kidneys, and to the spleen It also allows a systematic examination of the small intestine, if necessary It is the only incision that allows the ascending and descending colons to be easily and properly repaired and in addition, its posterior extremity is a convenient situation for an artificial anus at the site of the colon wound It is not a convenient incision for the stomach, except for that portion situated near the spleen

A similar incision starting behind and prolonged forward, if necessary, can be used with advantage in exploring lateral wounds of the body in the neighbourhood of the cæcum and sigmoid A subcostal incision is also good in certain liver wounds

In some cases of wounds in the back of the loin it is better to open the abdomen in the mid line and make sure that the peritoneum has not been involved If this is so, the wound is closed and the loin opened up and the necessary steps taken to deal with the condition found It is always very important when there is a possibility of a colon wound, to do everything to prevent contamination of the general abdominal cavity Such horizontal wounds suture easily and heal kindly

2 *Its closure* —The method of closure must depend on the condition of the patient If the condition is critical it must be closed by through and through sutures If there is time an attempt should be made to close the peritoneum separately, as many of these wounds—more than one would like—suppurate, and it is impossible to prevent this suppuration extending to the intestines if the peritoneum is unsutured If the condition of the patient allows it the wound can be closed in layers, but in every case there should be at least three through and through supporting stitches

Suppuration in the operation wounds has been a trouble. It may be partly due to defective technique, but in many cases one has to remember that the blood in the abdomen which must well out when the cavity is opened, is full of micro-organisms , and various methods have been tried to prevent infection but with no great success Of late, however, there seems to have been a certain amount of improvement It is curious that the same condition of things is found on operating on acute appendix abscess, where the peritoneum can readily combat the septic condition in which it is left while the abdominal wound falls a victim to the bacilli

3 *Abdominal drainage* —Opinions differ about this, and personally I never use it myself, nor do I believe that it has any points to recommend it When speaking of abdominal drainage I mean the ordinary drain to the pelvis or flanks It is quite another thing to tie a small local drain to a suture line which one mistrusts, the idea of which is to form a local track in the case of a leak.

4 *Flushing the abdomen* —Some people favour this procedure and it has a good deal to be said for it when the abdomen is full of septic blood At the same time it is difficult to do efficiently without much exposure of the intestines In small local infections without blood it is not to be recommended Both saline and eusol have been used, but to heat the latter to the requisite temperature is to destroy its efficiency The cold produced by ether is sufficient to damn it, even if its use could cleanse the abdomen A small amount used to produce leucocytosis finds favour with some.

POST OPERATIVE TREATMENT

I do not know that there is anything particular to be done to the patient after operation more than is done in ordinary surgical practice after any severe operation The question of infusion or transfusion will naturally arise and in some cases may be beneficial Most people treat their cases in a semi recumbent position As to the administration of morphia, it is better to give it than withhold it if the patient is restless or in pain Most interest turns on the condition of the bowels Castor oil, calomel and pituitrine all have their advocates There can be no doubt that pituitrine is a very fine purgative, especially if injected into the muscles , sometimes it requires to be helped by a glycerine enema Like all other purgatives, it is dependent for its action on a healthy condition of the musculature of the bowels and if this is paralysed either by shock or sepsis it will fail to act, as do other purgatives I am not particularly anxious about the opening of the bowels, and I am fairly convinced in my own mind that the bowels will not give trouble if the case is going to do well, and if the case is not going to do well—and it is mostly a matter of peritoneal sepsis—no purgative is of any real avail I think I have seen a good deal of discomfort needlessly inflicted upon people by attempts to make the bowels act

WOUNDS OF PARTICULAR ORGANS

The Œsophagus

Wounds of the œsophagus are very rarely seen, while wounds of the trachea are not so uncommon The rarity of wounds of this tube must, I think, be due to the fact that antero posterior wounds involve the spine and transverse wounds involve the great vessels Some of the lower thorax wounds, which are accompanied by vomiting, may be wounds of the œsophagus, but there is really no proof of this

One curious case may be quoted where a man was hit in the back about the fourth right interspace He was treated for a thoracic wound as there were no localising symptoms Two days later he passed the core of a bullet and the day following the mantle

Stomach

Organs wounded with the stomach —The thorax is involved in a fair number of cases The organs wounded with the stomach in order of frequency are the small gut, liver, colon, spleen, kidney, pancreas One case may be quoted as showing how complicated these wounds may be In this case the stomach, small gut, transverse colon, and sigmoid flexure were all wounded together The complicated wounds are usually side to side wounds of the body, or such wounds with an up-and down inclination

I have seen one curious case in which the anterior wall was grooved and the spleen and the kidney also wounded This ended fatally A curious fact is the rarity with which wounds of the spleen and the stomach are met with in association, and when so associated are nearly always fatal

Nature of wounds —The stomach affords many types of wound, nearly all easily explained by the nature of the projectile and the course it takes Sometimes the stomach wall is exposed by the carrying away of the anterior abdominal wall At other times prolapse of the stomach takes place, accompanied by that of the colon, small gut, and spleen

Bullets passing in an antero posterior direction make small perforations Shrapnel balls cause larger perforations, the edges of which are more excoriated than is the case with bullet wounds, the larger size and the rounder form of the ball causing a bruising of the wall before it bursts its way through Shell and bomb fragments make wounds commensurate to their size and shape When the axis of the flight of the projectile becomes more or less parallel to the walls of the stomach, the wounds become larger—sometimes a linear slit, sometimes a linear slit followed by a perforation to which the name of "note of exclamation" wound may be given When the projectile passes in through the epigastrium and out by the axilla the slits may become more or less parallel to the greater curvature When the missile passes in about the nipple line and takes a downward and oblique direction towards the right, the wounds are more or less at right angles to the greater curvature, so that the anterior wall of the stomach, or its antral portion, may be almost completely divided

Projectiles hitting the greater or less curvature in an antero posterior direction sometimes cause rather extensive V shaped injuries involving both walls Bruises or cuts in the peritoneum or muscular coats are also met with, and in one case a piece of hard clay which had perforated the spleen was found lying embedded in the stomach wall (Captain J Fraser)

It is important to remember that the posterior wall may be alone wounded or it may be wounded in conjunction with the posterior wall of the transverse colon Both of these wounds may be invisible when the abdomen is opened

The mucous membrane does not pout when the wounds are small, but in the case of linear wounds it becomes extruded just as it does when one incises the stomach wall in doing a gastro jejunostomy The anterior wall is the wall most frequently wounded

Bleeding —Wounds of the stomach are accompanied by very severe hæmorrhage, this is a cause of death in a considerable number of cases The hæmorrhage as a rule, does not come from the actual wall, but from the vessels as they run up and down the surface of the organ The hæmorrhage may take place either into the stomach or into the peritoneum

Possibility of spontaneous recovery —This has already been admitted, and it only remains to be said that a great many of the injuries could not result in this favourable termination

Symptoms —Vomiting is a very constant feature, in fact, the stomach is the only viscus which almost always furnishes this symptom One is often surprised that vomiting is possible with the size of the wound in the organ There is sometimes an escape of gas from the wound, but no particular diagnostic value is to be attached to the presence or absence of liver dullness

Treatment —Operation is to be advised in all cases except those cases already referred to where from the track of the bullet the wound is most probably situated near the œsophageal or upper portion of the cardia. The best incision is a paramedian one As a rule, one can tell if the posterior wall is likely to have been involved If this is the case or if there is any doubt, the posterior surface must be explored through the gastro-colic omentum in the usual way The suture of such wounds may be very difficult, as are wounds of the lesser curvature involving both surfaces There is no need to excise the wounds unless they happen to be very ragged Gastro-enterostomy may be necessary in cases of wounds dividing the antral portion or the duodenum, or in some cases of narrowing of the stomach This should only be done in cases of very evident necessity

Prognosis —The maximum period of successful suture after receipt of the wound is 36 hours and the prognosis depends largely on the amount of hæmorrhage that has taken place and on the association of other wounded organs As was seen in Table I (April 14th, p 566), the mortality mounts very quickly in complicated wounds The amount of peritonitis present does not depend very directly on the length of time between the injury and the operation

Secondary complications —A secondary hæmorrhage has proved fatal in an unsutured wound on the fifth day Major T R Elliot and Captain Herbert Henry have made some important remarks on "After History of Both Operated and Unoperated Gastric Wounds"[2] They showed that sutured and non sutured wounds, and contusions are subject to ulceration, secondary hæmorrhage, and perforation Secondary hæmorrhage occurred on the sixth, twelfth, and fifteenth day respectively, death occurred on the ninth, twenty sixth, and the twenty fifth day, the first from hæmorrhage and the last two from peritonitis Major Elliot thinks that this points to the necessity of careful feeding and especially to the withholding of extractives Subdiaphragmatic abscesses have been met with, but were not common even in the preoperative days, according to Sir George Makins.

Mortality and cause of death —The mortality can be judged from the tables The causes of death are shock and hæmorrhage and peritonitis at a later period The occurrence of many deaths from hæmorrhage teaches the lesson that stomach wounds cannot be considered as innocuous

The Small Intestine

Frequency —The small gut was perforated in 363 cases in 965 operations It is wounded by itself or in conjunction with nearly all other organs but especially with the colon and stomach and bladder

Character of the wounds —The character of the small gut wounds varies in some degree with the projectile that caused them but not to the extent that one might expect A bullet may inflict as severe an injury as a piece of high-explosive shell It used to be thought that a patient shot with a bullet had a better chance than one injured by a shell fragment The present war has proved this to be a mistake As a matter of fact, the least severe wounds are caused by the small bomb fragments The greatest number of lesions was 20, in a man who made a good recovery after resection of 6 ft The greatest number of lesions sewn up successfully was 14

Bullet injuries —The injury may be complete or incomplete—i e it may open the lumen or it may only excoriate bruise or tear the outer coats The most common injuries are the perforations made by the bullet striking the intestine at right angles to its long axis Here there are two perforations through which the mucous membrane pouts to form a small round rosette Some holes are said to be so small as hardly to admit a bullet, and in such holes the mucous membrane does not pout Apparently, as the flight of the bullet becomes more inclined to the transverse or long axis of the gut the perforations become slits but there are still two separate wounds These wounds gape somewhat, and the mucous membrane overlaps the cut muscular coat, so that a considerable mucous surface meets the eye The general appearance still suggests a rosette The two slits may enlarge until the continuity of the intestine is only maintained by two narrow strands of the wall.

---

[2] Brit. Med Jour April 8th 1916

In other cases there is only one wound involving different portions of the circumference of the intestine, it may reach from near the mesenteric border to near the free margin or involve the free margin only In other cases the free margin is slit right back to the mesenteric border, so that only a narrow strip of wall remains It is remarkable that the last piece to be divided is usually the attached portion Here there is a wide gaping wound with an extensive exposed mucous surface In extreme cases the gut is completely divided In another extreme form of injury the intestine is only represented by a long narrow strip of bowel, its appearance suggests that some animal had gnawed or worried it

The explanation of the transverse direction of the lesions is to be found in the looped arrangement of the small intestine whereby a greater part of the tube lies in a vertical direction As a man is usually shot either from side to side or from before backwards, the missile will usually hit the intestine at right angles If the bullet takes an up-and-down direction one meets with longitudinal lesions of the gut

Shell fragments —Shell fragments cause wounds of all varieties generally commensurate to their size

Shrapnel balls —These cause large ragged perforations and tears

Bombs —Bomb injuries often cause small multiple wounds and the same may be said of small fragments of high-explosive shell or a disintegrated bullet

The cause of the eversion of the mucous membrane is, on the one hand due to the redundancy of the mucous membrane and also apparently from an examination of microscopic sections to a retraction of longitudinal coat (Captain J W McNee and Captain J S Dunn) Microscopic examination of the wounded edges also shows that the lesion is a very local one, in fact the appearances are no more than one would expect to see if the intestines had been cut with a pair of scissors—it usually consists of a blood infiltration in the neighbourhood of the wound Mucous membrane stains well and distinctly right up to the very tear

As many as 20 injuries may have to be dealt with. They may be even or uneven in number and when uneven the projectile is often found within the gut or, if even it may still be found lying in the last hole of exit. Very often the projectile is never found remaining lodged in the body, or it may be passed per anum As a rule the injuries are found fairly close together but if multiple they may involve a long extent of the intestine (9 ft). In a few cases small lesions are distributed over the total length of small intestine Sometimes a knuckle of gut is prolapsed and even strangulated in the abdominal wall Sometimes the exposed knuckle is perforated at other times it is intact but there are perforations within

Symptoms —There is nothing more to be added to that which has been said under the heading of "Diagnosis of Intraperitoneal Damage

Treatment —A long paramedian incision is the rule, except in those cases which have been dealt with when the site of the incision was discussed. The actual operative technique in the abdomen is as follows If present the blood must be got rid of and the bleeding stopped As a rule the whole length of the small intestine must be explored with the possible exception of those cases of side-to-side wounds involving one half of the abdomen where a transverse incision shows that the colon has been involved alone If there is no blood and the length of the missile s track can be seen it may be possible to exclude small gut injury The cæcum or duodeno jejunum junction is first picked up and brought out of the wound, then the intestine is inspected taking care to look at both sides, and the examined part is replaced within the abdomen. If a small hole is found and the gut beyond it for 6 or 8 inches is intact the hole is sewn up one suture being as a rule, sufficient If the next lesion that is encountered is a small one the process may be repeated If however, the first lesion is a large one it is better to cover it up with gauze and a clamp and to proceed with the examination of the whole length, because a big lesion, if quickly followed by another, may necessitate resection, and the amount to be resected can only be determined when the total injuries are known

When the small intestine has been dealt with the stomach is explored if there is any likelihood of its being injured, and the colon is dealt with last of all, as it is here that an artificial anus may be very likely necessary If a horizontal incision is used it may be better to deal with the colon first, as thereby soiling of the peritoneum is minimised

Turning to the question of suture *versus* resection, it may be said that small and discrete injuries mean suture, while multiple or severe injuries, especially if close together, mean resection Resection is also necessary if four inches of the mesentery is destroyed or infarcted. In some cases double resections have been necessary where there were two badly injured portions of the intestine lying far apart.

I would advise that suture be practised on every possible occasion, even if there are two or three almost complete gashes, provided they are not too close together and so long as the gut remains undivided It is better to narrow the gut somewhat than do a resection The general tendency amongst operators has been to abandon resection

Circular versus *lateral suture* —It may be said that this old controversy is still unsettled, opinion sways backwards and forwards, and I cannot see from statistics that we have got that there is any difference. If lateral anastomosis is practised the lateral openings should be made a little way from the divided ends, because it is these divided ends which last recover their motility

Primary short-circuiting or enterostomy —The idea of these operations is to relieve the upper segment of the bowel which is liable to dilatation from a nervous or septic cause It has by no means found universal acceptance, and I myself should not recommend it as a primary measure—it may be useful in some of the later operations Naturally a small gut anus is to be avoided whenever possible, but it may be the only thing to do

Treatment of a prolapsed knuckle —In the early days there was some difference of opinion on what was the best treatment for this condition Nowadays with the establishment of the operative treatment there is no doubt that the right thing to do is to open the abdomen and deal with the lesions which are found.

Prognosis —In the first instance one may say at once that wounds of other organs increase the gravity of the prognosis Wounds of the duodenum have been so far very fatal, but with this exception there does not seem to be any difference between the jejunum and the ileum Possibly it is more important to take greater care with the suture line in the case of the jejunum in consequence of the presence of bile and pancreatic fluid Some people think that the jejunal contents are more irritating and cause greater pain than those of the ileum

Time factor —This has been already dealt with and it only need be again mentioned that hæmorrhage is a great bugbear and causes early deaths It may also have a distinct bearing on the later deaths from peritonitis by spreading infection in the abdomen As regards sepsis, to judge from the peritonitis present, it may have made considerable headway in four hours and may be practically absent after 26 hours As regards prognosis, more stress is to be laid on paralytic distension of bowel than on the amount of lymph or fluid effused

Mortality and causes of death —The mortality can be seen from the general table at the end of Lecture III Death, when it occurs in a few hours is due to shock and the results of hæmorrhage When it occurs later it is caused by peritonitis which usually ends fatally between the third and fifth day

---

BRISTOL ROYAL INFIRMARY —At the annual meeting the medical report showed that 4455 military in patients were admitted to this institution In addition, 3733 in patients were treated, being an increase of 252 compared with 1915 The out patients numbered 48 944 The financial statement showed the ordinary income was £15 472 and the ordinary expenditure £23 976. Bequests amounting to £40 891 had been received, being £35,586 more than in the previous year The debt on the institution was now £14,802

STUDIES IN WOUND INFECTIONS

ON THE QUESTION OF BACTERIAL SYMBIOSIS IN WOUND INFECTIONS

(*From Inoculation Department, St Mary's Hospital*)

FOR many years it has been recognised that one species of micro organism may exercise a helpful action on the proliferation of another when the two are grown together in the same culture medium Earlier examples of this type of symbiosis—the term usually applied to this phenomenon—are (1) the growth of an anaerobic bacillus in association with an aerobe, (2) the growth of such a bacillus as *B influenzæ* in association with either staphylococcus or *B xerosis*

With regard to the first example given above in which an aerobic micro organism enables an anaerobic one to grow freely, the explanation usually given is that the aerobe in its growth absorbs the oxygen, thus making the conditions favourable for the proliferation of the anaerobe This principle has been frequently employed in the cultivation of anaerobes and numerous ingenious methods have been devised for thus utilising the oxygen absorbing properties of *B subtilis* and other bacteria

In respect to the second example given in which the growth of *B influenzæ* is assisted by the presence of another micro organism such as staphylococcus no such simple explanation can be given, but it is certain that the staphylococcus furnishes a substance which enables the influenza bacillus to flourish on a medium on which it will not grow alone and also enables it to maintain its vitality for long periods

In connexion with septic wounds of the present war the question of symbiosis may assume very considerable importance In all these wounds the bacterial flora is a varied one consisting as it does of anaerobic and aerobic, spore bearing and non sporing bacteria As has been shown by Fleming,[1] the primary infection of the wounds is a fæcal one At first there is a phase in which the anaerobic spore bearing bacilli (*B perfringens* and organisms of putrefaction) flourish together with streptococci, *B proteus*, and diphtheroids The anaerobic bacilli as time goes on gradually disappear, and ultimately there remain streptococci, staphylococci, diphtheroid organisms, and, at times, *B proteus*

The microbes (apart from *B tetani*) which directly cause the most serious infections are in the early stages of the wound, *B perfringens*, possibly *B malignant œdema* and streptococci while in the later stages streptococci are responsible for almost all the serious complications Although the other microbes do not usually cause serious complications, their presence in the wound becomes an important matter if it can be shown that they may act as symbiotic stimulants to the growth of the more dangerous members of the bacterial flora The experiments detailed below indicate that this is the case

In order to approximate the conditions of the experiment to those obtaining in wounds the culture medium usually employed was human serum, either unaltered or serum to which sufficient trypsin had been added to neutralise the antitryptic power The *raison d'être* of this procedure was that Wright has shown that, according to their situation the bacteria proliferating in a wound have two varieties of culture media from which they obtain their nutriment

(i) Those proliferating in the cavity of the wound are supplied with a fluid medium which consists of the blood fluids altered to a varying degree by the breaking down of the extravasated leucocytes—a process which leads to the liberation of a large amount of trypsin According to the amount of trypsin thus set free the antitryptic power of these blood fluids is either diminished, completely neutralised, or the resulting fluid is even—and this is by no means an unfrequent stage—rendered strongly tryptic All these changes render the blood fluids a much more suitable pabulum for bacteria, for it has been shown that neutralisation of the antitryptic power of the blood serum completely destroys all the antibacterial properties of the blood and the presence of free trypsin together with albumens obviously leads to the formation of digestion products which are the best of all foods on which to cultivate bacteria

(ii) Those bacteria proliferating in the lymph spaces of damaged but still living tissues are bathed in a fluid consisting of lymph altered to a much slighter extent, according to the time it has been exuded from the vessels, the number of leucocytes it contains and other, at present, unrecognised factors

PART I —*Do the Other Microbes Present in a Wound Aid the Growth of* B perfringens *?*

Fleming[2] in some preliminary experiments has shown that staphylococci, streptococci, and *B proteus* when grown in association with *B perfringens* caused an increased growth of this latter micro organism

Before proceeding to give the details of the various experiments the following points concerning the growth of *B perfringens* in culture should be mentioned

B perfringens when planted into fresh serum and incubated under anaerobic conditions will only grow when the sowing is a heavy one

Wright has shown that if the antitryptic power of the serum is neutralised by the addition of trypsin or its alkalinity is neutralised with an acid growth occurs with a much lighter sowing

When growth takes place in serum a very large quantity of gas is formed, so that four to five volumes of gas may be produced from one volume of serum This circumstance affords a convenient index of the presence and also of the amount of growth

Experiment I Influence of staphylococci and streptococci on growth of B perfringens *in milk* —A broth culture of *B perfringens* was diluted with broth 10-fold, 100-fold, and by 10-fold steps to a million fold dilution 40 c mm of each dilution was planted into (*a*) milk 1 c c , (*b*) milk, 1 c c + 20 c mm staphylococcus broth culture, (*c*) milk, 1 c c + 20 c mm streptococcus broth culture These tubes having been incubated for 24 hours were examined for growth which was indicated by the formation of the typical clot and gas formation The results are shown in Table I —

(*b*) + staphylococcus		,	Gr	Gr	Gr	Gr
(*c*) + streptococcus						

Gr = growth

Experiment II Influence of diphtheroid bacilli on growth of B perfringens *in serum (with and without the addition of trypsin)* —In this experiment pieces of 6 mm bore glass tubing about 15 cm long and sealed at one end were used as culture tubes Into these miniature test tubes the culture materials and micro organisms were introduced and then melted vaseline was run on to the surface to form a column about 2 5 cm high The index of growth was gas formation evidenced by the vaseline being pushed up the tube Dilutions of *B perfringens* broth culture having been made as in Experiment I , 10 c mm of each was planted into 300 c mm of serum Another 10 c mm of each dilution was planted into a similar tube of serum which had been thickly sown with a diphtheroid bacillus The experiment was then repeated, using serum to which sufficient trypsin had been added to neutralise the antitryptic power The results are shown in Table II

---

[1] THE LANCET 1915 ii 638

[2] THE LANCET 1915 ii 376

Two and a half hours after planting these cultures showed gas formation in the first tubes of series (*b*) and (*d*) and in four hours the amount of gas produced in the first tube of series (*b*) was equal in bulk to the culture fluid Such rapid gas formation has not been noted under any other condition

Experiment III Do all the diphtheroids commonly present in wounds stimulate the growth of B perfringens *to the same extent?*—Fresh human serum was divided into portions and each portion was planted thickly with a strain of a diphtheroid bacillus The diphtheroid bacilli employed were representatives of the various groups frequently found in wounds

Two hundred and fifty c mm of the serum containing the diphtheroid bacillus were distributed into miniature test-tubes, as described in Experiment II, and to each were added 50 c mm of dilutions, as shown below, of a *B perfringens* broth culture (four days old) Vaseline was then poured on the top of the fluid and the tubes were incubated for five days The results are given in Table III. —

TABLE III

Strain of diphtheroid used	Dilution of *B perfringens* culture

Driscoll II			0	0
Control*	0	0	0	0

* Without diphtheroid *B perfringens* only

From the above table it will be seen that these diphtheroids all stimulate the growth of *B perfringens* in serum and approximately to the same extent

Experiment IV Influence of a coliform bacillus and B proteus *on growth of* B perfringens *in serum*—Similar small tubes to those used in former experiments were filled in as follows —

Tube A Serum 1 c c + *B perfringens* emulsion 10 c mm
B Serum 1 c.c + *B perfringens* emulsion 10 c.mm + coliform bacillis emulsion 10 c.mm.
C Serum 1 c.c + *B perfringens* emulsion 10 c mm + *B proteus* emulsion 10 c.mm.

These tubes were incubated anaerobically for 18 hours and the number of *B perfringens* estimated by counting against the number of the red blood corpuscles (Wright's method) The results obtained were as follows —

B perfringens per c c Tube A, 62 millions, Tube B, 146 millions, Tube C 357 millions

Experiment V To ascertain, when two microbes are grown in symbiosis, whether both are stimulated to increased proliferation—The micro-organisms employed in this experiment were *B perfringens* staphylococcus, and streptococcus Miniature test tubes containing 1 c c of the fluid from an ovarian cyst were planted with cultures as shown below After incubation under anaerobic conditions for two days, the number of microbes was estimated by counting them against the number of red blood corpuscles in a film (Wright's method) and also in the case of the aerobic micro-organisms, by diluting and planting a known quantity of a dilution on to plates which were then incubated under aerobic conditions the resulting colonies being counted after a suitable interval The results are given in Table IV —

TABLE IV

No of tube	Micro-organisms planted into the ovarian cyst fluid *	No of microbes per c c estimated by Wright s method after incubation	No of cocci obtained by plating 20 c mm of the fluid diluted 600 fold after incubation
I	*B perfringens* emulsion	360 million	—
II	*B perfringens* emulsion + staphylococcus emulsion	*B perfringens* 433 million staphylococcus 800 million	Innumerable colonies of staphylococcus
III	Staphylococcus emulsion	400 million	About 1500 colonies †
IV	*B perfringens* emulsion + streptococcus emulsion	*B perfringens* 620 million streptococci 1 0 million.	265 colonies of streptococcus
V	Streptococcus emulsion	50 million	colonies of streptococcus

* In each instance 10 c mm of emulsion was planted
† Certainly less than half the number of colonies obtained from Tub II

This experiment shows conclusively that when *B perfringens* is grown in symbiosis with either staphylococcus or streptococcus the stimulation to increased growth is mutual to both species of bacteria

Experiment VI Influence of streptococci and staphylococci on the growth of B perfringens *in serum*—In this experiment the technique was modified by growing the cocci in serum for three days before planting the *B perfringens* Three small test tubes, each containing 1 c c serum, were taken, one was planted with streptococcus, another with staphylococcus, while the third was left uninoculated All three tubes having been incubated together anaerobically for three days an equal amount of *B perfringens* culture was added to each After a further incubation for 18 hours the number of *B perfringens* were estimated by Wright's method

Tube I (staphylococcus + *B perfringens*) contained 120 million *B perfringens* per c c.
II (streptococcus + *B perfringens*) contained 430 million *B perfringens* per c.c
III (*B perfringens* only) contained 62 million *B perfringens* per c c

The above experiments show that the growth of *B perfringens* is greatly increased when it is grown symbiotically with either streptococcus, staphylococcus, or various diphtheroid bacilli It might be argued, however, that this increased growth was simply due to some simple action such as the neutralisation of the alkalinity or the antitryptic power of the serum, both of which as mentioned above have been shown by Wright to aid the growth of this bacillus The following experiment shows, however that the beneficial action of symbiosis with streptococci, diphtheroid, and a coliform bacillus is just as marked in the case when the serum, employed as culture medium has previously been neutralised either in respect to its alkalinity or its antitryptic power

Experiment VII—The technique employed was similar to that used in Experiments II and III

TABLE V

PART II.—*Do the Various Micro-organisms Commonly Found in Wounds Favour the Growth of Anaerobic Bacilli other than* B perfringens?

Experiment VIII Influence of streptococci on the growth of the bacillus of malignant œdema in serum—A broth culture of malignant œdema was diluted by ten fold steps up to a million fold dilution Of each of these dilutions 40 c.mm were planted into a series of tubes containing 1 c c of serum and also into a series containing 1 c c of serum previously planted with streptococci Vaseline was poured into the tubes to make a column 2 5 cm high and the tubes were then incubated at 37° C for five days The results then were as shown in Table VI —

TABLE VI

Series of tubes	Dilution of broth culture of malignant œdema						
	1	$\frac{1}{10}$	$\frac{1}{100}$	$\frac{1}{1000}$	$\frac{1}{10000}$	$\frac{1}{100000}$	$\frac{1}{1000000}$

(B) With	Gr	Gr	Gr	Gr	Gr	Gr	Gr

Gr – *growth*

Experiment IX Influence of diphtheroid bacilli, streptococci, and staphylococci on the growth in serum of the bacillus of malignant œdema and B Hibler IX —A quantity of serum was divided into two portions, one of which was implanted with the bacillus of malignant œdema, the other with *B Hibler IX* These implanted sera were now distributed in two series of minute test-tubes, 0 2 c c being added to each One tube of each series was kept as a control, the others being further implanted with a different micro organism Melted vaseline was now poured on to the surface of the fluid and the tubes were incubated at 37° C After varying intervals the tubes were examined for growth of the anaerobic bacillus which was demonstrated by the formation of gas The results are shown in Table VII —

TABLE VII

Other micro-organism planted	Serum planted with the bacillus of malignant œdema			Serum planted with *B Hibler IX*		
	Time of incubation in days—					
	3	5	9	3	5	9
None	0	0	0	0	Gr	Gr
Diphtheroid No I	Gr	Gr	Gr	Gr	"	"
No II	"					
Streptococcus fæcalis						
Staphylococcus				0	"	

From these two experiments it is seen that the ordinary non sporing microbes found in wounds greatly stimulate the growth of the malignant œdema bacillus and *B Hibler IX*, both of which have been said to cause gas gangrene

PART III —*Do the Other Microbes Commonly Present in a Wound Favour the Growth of Streptococcus?*

As streptococcus is the cause of many of the complications, such as cellulitis or septicæmia which occur even in the earlier stages of wounds and, in the later stages, is the one markedly pathogenic microbe, with the exception of staphylococcus, that is almost constantly present, any condition which favours its growth must be at once recognised as of great importance In the earlier stages the associated microbes are usually *B perfringens* putrefactive anaerobic bacteria *B proteus*, and diphtheroid bacilli, while in the late stages it is associated with diphtheroid bacilli, *B proteus*, and staphylococci

Throughout these experiments in determining the amount of streptococcal growth the total number of cocci were counted by Wright's method or the number of living cocci were estimated by diluting the culture and plating out a known quantity of a dilution on an agar plate

Experiment X Influence of B perfringens *on the growth of streptococcus*

Tube I 1 c c fresh human serum planted with 10 c mm. streptococcus emulsion
II 1 c c fresh human serum planted with 10 c mm streptococcus emulsion + 40 c.mm *B perfringens* broth culture

After incubation for 18 hours under anaerobic conditions the number of streptococci was counted by Wright's method

Tube I (streptococcus only) contained 100 million streptococci per c c.
II (+ *B perfringens*) 360

Experiment XI Influence of B perfringens *on growth of staphylococci and streptococci* —Four tubes, each containing 1 c c of serum, were taken Two of them were planted with *B perfringens* the other two remaining unplanted After all the tubes had been incubated together for 24 hours under anaerobic conditions an equal quantity of staphylococci culture was planted into one of the unplanted tubes and into one of the *B perfringens* cultures The remaining tubes were similarly planted with streptococcus. After having been incubated under anaerobic conditions for 24 hours each culture was diluted 1000-fold with broth, and 10 c mm of this dilution was distributed on to the surface of an agar plate These plates were incubated under aerobic conditions, and the resulting colonies of streptococcus or staphylococcus were counted The results are shown in Table VIII —

TABLE VIII

Tube I (*B perfringens* + staphylococcus) gave about 600 colonies of staphylococcus
II (Staphylococcus only) gave 64 colonies of staphylococcus
III (*B perfringens* + streptococci) gave about 1000 colonies of streptococci
IV (Streptococci only) gave 1 colony of streptococci

When it is considered that both streptococci and staphylococci grow much more readily in unaltered serum than *B perfringens* this enormous stimulation of growth is all the more surprising

Experiment XII Effect of diphtheroid bacillus on growth of streptococci —Into each of three small test-tubes 1 c c of serum was placed To the first was added 10 c mm of 1000-fold diluted broth culture of a streptococcus, to the second 10 c mm of 1000-fold diluted broth culture of a diphtheroid bacillus, and to the third 10 c mm of the 1000-fold diluted streptococcus culture and 10 c mm of the 1000-fold diluted diphtheroid bacillus culture The number of living micro organisms in each tube was then estimated by plating out a known quantity on agar and counting the resulting colonies The three tubes were then incubated for 10 hours at 37° C, after which the number of living micro-organisms was again estimated by the same method. The results are given in Table IX —

TABLE IX

No of tube and implantation *	Content of living streptococci per c.c		Content of living diphtheroid bacilli per c.c	
	At time of planting	After 10 hours incubation	At time of planting	After 10 hours incubation
1 Streptococcus culture	13 000	2,800 000	—	—
2 Diphtheroid culture	—	—	2000	5,300,000
3 Streptococcus culture and diphtheroid culture	13 000	120 000 000	2000	2,600,000

* In each instance 10 c mm of broth culture diluted 1000-fold

This experiment shows a very great increase in the numbers of streptococci in Tube 3 where streptococci are grown in association with diphtheroid bacilli In this tube there was after 10 hours more than 40 times as many streptococci as in an exactly comparable tube where the streptococcus was grown by itself

Association with streptococci did not appear to favour the growth of the diphtheroid bacilli, on the other hand it seemed to retard it, as there were only half the number of living diphtheroid bacilli in the tube containing the mixed culture as there were in the tube in which the diphtheroid bacillus only had been grown

With regard to the mechanism by which the aerobic organisms help the anaerobes the following *experiment* is of interest

Experiment XIII —An ordinary broth culture tube was incubated with a diphtheroid bacillus such as is commonly found in wounds The cotton wool plug was cut off short and pushed a little way down the tube Melted vaseline was now poured on the plug so as to soak into it and to leave a layer of vaseline about 0 5 cm thick on the top The tube was put in the incubator, and when it had reached incubator temperature a mark was made at the upper level of the vaseline As oxygen was absorbed from the tube so the vaseline was sucked down, and at intervals marks were made corresponding with the level of the vaseline

The height of the column of air in the tube was 87 mm

In 6 days the vaseline was sucked down 7 5 mm = 0·09 of total volume
In 10 " " 13 5 mm = 0·15
In 4 months 17·5 mm. = 0·2

We see, then, that ultimately the amount of gas absorbed was 0·2 of the total volume, which corresponds with the amount of oxygen in air, and the absence of oxygen was confirmed by the introduction of pyrogallic acid and caustic soda, when no further absorption took place and no brown colour was produced

Further experiments showed that staphylococcus, streptococcus *B pyocyaneus*, and some coliform bacteria absorb oxygen to a greater or less extent during their growth

While this oxygen absorptive power may play some part in the symbiotic action of aerobic bacteria on the anaerobes yet it cannot be the only explanation as the experiments cited above show that the stimulant action of the "aerobic" bacteria is exercised when the cultures are grown under absolutely anaerobic conditions

Summary and Conclusions

Part I.—The experiments described show that —

(i.) The proliferation of *B perfringens* is much more rapid when it is grown in symbiosis with streptococcus, staphylococcus, various diphtheroid bacilli, *B proteus*, *B pyocyaneus*, and a coliform bacillus

(ii) Such increased growth occurs equally well when the culture medium consists of fresh serum or of serum which has been neutralised either in respect of its alkalinity or its antitryptic power, indicating that the increased proliferation in fresh serum cultures is not due to either of these changes taking place.

(iii.) All strains of diphtheroid bacilli, commonly isolated from wounds, were found to be practically equally efficient in stimulating the growth of *B perfringens*

(iv) Not only were a much larger number of *B perfringens* found in the cultures grown in symbiosis with these various bacilli after a certain period of incubation, but it was also found that an almost infinitely smaller number of *B perfringens* would proliferate under these conditions than when pure cultures were made

(v) When *B perfringens* and streptococci are grown in symbiosis a much more abundant growth of *both* microbes results

Part II—The experiments detailed show that —

(vi) Nos (i) (ii.) and (iv) of the above conclusions applied equally when the bacillus of malignant œdema or *B Hibler IX.* was substituted for *B perfringens*

Part III—The experiments described show that —

(vii.) *B perfringens* when grown in symbiosis not only with streptococci, but also with staphylococci leads to an enormous increase in the number of cocci found in the culture

(viii) Streptococci grown in symbiosis with diphtheroid bacilli gave a much more abundant growth than when grown in pure culture. The growth of the diphtheroid bacilli in the mixed culture was, however, 50 per cent less than in the pure culture

(ix.) The final experiment shows that diphtheroids and many other bacilli have the power of absorbing oxygen to a greater or less extent during their growth, but that this property will not account entirely for the increased proliferation that occurs, when aerobes and anaerobes are grown in symbiosis, since similar mixed cultures placed under anaerobic conditions show quite as marked an increase of growth

These experiments indicate that bacterial symbiosis may play a very important role in wound infections For as regards gas gangrene which is caused by the invasion of the tissues by certain anaerobic bacilli, the commonest being the *B perfringens* it is well known that very large doses of pure cultures of this bacillus have to be inoculated into animals in order to produce this disease with certainty, again Wright has shown that to obtain a growth of this bacillus in serum a very heavy implantation is necessary but if the serum is altered by neutralisation of its alkalinity or its antitryptic power a very much smaller sowing will produce an abundant culture From these experiments he concluded that the conditions leading to such an alteration of the blood fluids play an important part in the production of gas gangrene.

Taking these facts into consideration, together with many of the clinical aspects of gas gangrene it would seem apt to compare the action of *B perfringens* in the production of this disease with a high explosive which is comparatively harmless until the explosive action is started by a detonator Keeping this simile in view it is obviously of the utmost importance to ascertain those conditions which act as 'detonators' in the growth of this bacillus and the experiments detailed above show that over and above those factors which have been described by Wright there is another—namely symbiosis—and that this is in *in vitro* experiments the most important as yet described since the growth of *B perfringens* obtained in serum under such conditions is not only much more rapid in development and more copious in quantity, but also follows the lightest implantations

These results would, for example explain the occurrence of gas gangrene in those cases where the number of bacilli introduced into the wound at the time of its infliction was comparatively small They would also explain the frequent occurrence of gas gangrene in those cases in which after a thorough cleansing and opening up of the wound—a procedure which should reduce the infection to a minimum—free drainage is prevented either by suture or unsuitable dressings Again these experiments would explain the almost "explosive" onset of gangrene in some of the severe, heavily infected wounds for the results obtained in Experiment II, in which, within four hours, gas equivalent to the volume of the serum used as a culture medium was produced, indicate a rate of growth which has never been approached under any other conditions

These experiments show also that the streptococci multiply much more rapidly when grown in symbiosis with various bacteria, amongst these being the group of diphtheroid bacilli which are present in practically every infected wound from the earliest stage until cicatrisation is complete Such being the case it is very probable that symbiosis plays an important part in the production of cellulitis and similar complications due to streptococci occurring in the earlier stages of the wound, and also accounts for the common occurrence of the severe inflammatory reactions which so frequently follow operative interference in the later stages of the wound

CLINICAL TYPES OF SUBTERTIAN MALARIA

AS SEEN IN SALONIKA IN SEPTEMBER, OCTOBER, AND NOVEMBER, 1916

BY A. W FALCONER, M.D ABERD, M R.C P LOND,
MAJOR, R.A.M C. (T)
AND
A. G ANDERSON, M D ABERD, M R C P LOND,
TEMPORARY CAPTAIN R.A.M C

DURING last September, October, and November we had an opportunity of seeing over 3600 cases of malaria. The diagnosis of malaria has been founded either on a positive blood finding or on the history of the case, temperature chart, and a definitely hard palpable spleen In a small proportion of the cases other infections were present in addition In isolated cases a double infection with subtertian and quartan parasites was found Owing to the fact that in some 40 per cent. of the cases we were unable to demonstrate the parasites in the peripheral blood stream we are not in a position to give exact figures of the relative amounts of benign and subtertian infections, but there can be no doubt that during this period the percentage of subtertian infections was very high. The relatively high proportion of the negative blood finding is due to the fact that practically all the patients were under the influence of quinine on admission to the hospital and many of them had been several days under hospital treatment before admission to a base hospital. Further, owing to pressure on beds it was generally impossible, in the less severe cases, to make more than one blood examination.

The majority of the cases were of the simple subtertian, double subtertian and irregular types of subtertian pyrexia without local manifestations These cases uniformly responded well to treatment with quinine The most important group of cases with local symptoms on account both of relative frequency and of difficulty of differential diagnosis were characterised by more or less urgent gastro-intestinal symptoms This group could be separated into several more or less definite types

Dysenteric—A large number of the cases were sent into hospital with a diagnosis of dysentery A prominent symptom was the presence of diarrhœa. The great majority of the patients stated they were passing "blood and slime," but this is a mere formula with most of them and of no value in diagnosis. In most of these cases the stools were fluid and fæculent without definite blood or mucus, and they varied in number from 6 to 15 or more in 24 hours These cases rapidly improved under quinine. In a smaller number of cases the stools contained definite blood and mucus It was possible in the great majority of these cases to demonstrate a superadded infection with one of the organisms of the dysenteric group In a few other cases patients admitted with malaria but without dysenteric symptoms developed genuine bacterial dysentery, and again cases with bacterial dysentery, after a few days in hospital, showed genuine malaria with protozoa in the blood In a few cases where the diarrhœa tended to persist concurrent infections with *Lamblia intestinalis*, *Tetramitus*, *Trichomonas* and *Balantidium coli* were demonstrated Apart altogether from these cases there were a considerable number of patients admitted whose dominant symptom was diarrhœa, and in whom repeated examinations of the stools failed to demonstrate any dysenteric organisms or amœbæ Several of these cases died, and the autopsy showed, in some, slight congestion of the colon, chiefly in its upper part, in others, definite small submucous hæmorrhages, and in one, to be described in detail, extensive submucous hæmorrhages, but a perfectly intact mucous membrane In many of these cases the bowels moved at first from 20 to 30 times a day The stools were liquid, fæculent, and not unlike Worcester sauce In the majority this diarrhœa very speedily subsided under energetic quinine treatment In some the stools were fæcal, liquid, more or less heavily tinged with blood, and, very characteristic, notably bile-stained This stool, although containing blood and traces of mucus, is yet macroscopically quite distinct from the typical dysenteric stool As examples of those types we may quote the following cases —

Corporal F, aged 32, admitted on Sept 20th, 1916, with profuse diarrhœa and pyrexia The bowels were moving about every hour, stools fluid, fæculent, and heavily tinged with bile and blood Spleen enlarged and hard, blood film showed very heavy infection with subtertian parasites of all types, rings, rosettes, and crescents He was treated with intravenous quinine and salines The stools were examined for organisms of dysenteric group and protozoa with a negative result The diarrhœa continued, the stools constantly containing blood and traces of mucus Ultimately he became incontinent and died eight days after admission Post mortem, spleen was enlarged to four times normal size Large intestine showed moderate congestion with small punctate submucous hæmorrhages, no ulceration, and whole mucous membrane smooth and glistening

Sergeant B, aged 24, sent into hospital on Sept 2nd, 1916, with history of having been unwell for nine days, at first with constipation, abdominal pain, and vomiting Three days before admission he began to suffer from severe diarrhœa On admission he was collapsed and bowels moving every half hour, stools liquid, fæculent, and heavily stained with blood and bile Marked icteric tinging of sclerotics The blood showed the presence of numerous subtertian rings The diarrhœa continued and ultimately the motions appeared to consist of almost pure blood Post mortem, the whole of large bowel showed a microscopically intact smooth glistening mucous membrane without any suggestion of ulceration Extensive submucous hæmorrhages were present throughout whole of large bowel

Choleraic pernicious fever —Fortunately only two cases of this type were met with Both cases died within 15 hours of admission in spite of intravenous quinine and salines

Private K, admitted on Sept 14th, 1916, from a camp alongside our lines On admission was in state of profound collapse, with subnormal temperature, sunken cheeks, blue nails, and cold, cyanotic extremities Mentally he was dull, and it was difficult to get a history, but it appeared he had not been well for two days, although he remained on duty till day of admission Parasites not found in blood film There was incontinence of fæces, and a watery brown fluid without visible blood or mucus continued to ooze from anus He died within 12 hours of admission Post mortem, spleen was slightly enlarged and almost diffluent Colon and sigmoid flexure presented moderate congestion but no trace of ulceration Smears from spleen, after prolonged search, showed rings and crescents of subtertian malaria

The other case was exactly similar except that it was a second attack and that the parasite was readily found in the blood

Appendicular type —Cases strongly suggesting appendicitis have not been infrequent In all we have seen some 12 cases of this type The chief complaint was vomiting and severe pain referred to the right iliac fossa associated with moderate pyrexia and marked tenderness and rigidity in the right iliac fossa In most of the cases it was possible to show that the rigidity was not constant. In some of the cases the tenderness was most marked somewhat above McBurney's point, in others it corresponded accurately with this point. In all of our cases we were able to demonstrate either the presence of the parasite in the blood or a definite enlargement of the spleen None of our cases showed a leucocytosis, and all had the typical relative lymphocytosis of malaria. All rapidly cleared up under quinine treatment. We have also seen a few cases in which the abdominal pain and rigidity were so marked and so diffuse as to suggest an acute abdomen but these also rapidly cleared up under the use of quinine with the exception of one case which was complicated with septicæmia This at the autopsy showed a purulent pleuritis and peritonitis, in the exudates of which streptococci were demonstrated

Bilious remittent fever —Thirteen of our fatal cases were of this type These cases had all been ill several days before admission to the base hospital. On admission they were collapsed, with marked yellowing of the conjunctivæ and a peculiar earthy facies They suffered much from almost constant vomiting, and the majority from billious diarrhœa and mental confusion After treatment by intravenous quinine and intravenous saline they improved from a condition of apparently extreme urgency to one of relative comfort, but, unfortunately, the improvement was not maintained, and after a period of from two to five days their condition again became critical The jaundice became deeper, the vomiting, often accompanied by uncontrollable hiccough, again became severe, the bowels incontinent, the temperature rose, and they died in coma or delirium The chief macroscopic features post mortem were enlargement of the spleen and submucous hæmorrhages in various organs and the presence of a gall bladder distended with thick dark bile

Pernicious fever with pulmonary symptoms —Both numerically and as a cause of death the next most important group was that in which the patients' dominant symptoms were referred to the respiratory tract Of the cases of malaria which terminated fatally, pulmonary complications of a pneumonic or broncho-pneumonic character were present in 7, and were the immediate cause of the fatal issue. Amongst the patients admitted to the hospital were a large number who complained of respiratory symptoms, and some who were admitted under the varying diagnoses of bronchitis, broncho pneumonia, and congestion of the lungs, were found subsequently to be suffering from subtertian malaria. In them the malarial parasite could be demonstrated in the blood Amongst these cases were a small proportion who, in addition to their malaria gave a history and presented the physical signs of a chronic bronchitis and emphysema, and in them the occurrence of a malarial attack caused a decided increase in their symptoms and physical signs In the majority of cases, however, there was no history of bronchitis nor any evidence of emphysema Amongst these the pulmonary complications could be divided into the bronchitic, the broncho-pneumonic, and pneumonic

The bronchitic type —The patients complained of pain and tightness in the chest with persistent cough, accompanied by expectoration They presented the ordinary signs of a diffuse bronchitis with numerous rhonchi and râles scattered all over both lungs Some showed the typical malarial pyrexia, others an irregular intermittent pyrexia, while others ran a normal or subnormal temperature throughout their stay in hospital They differed from an ordinary bronchitis only in the presence in the blood of the malarial parasite, and their rapid response to treatment by quinine It is not suggested that the bronchitis is caused by the malarial parasite and it may be that the bronchitis is nothing more than that which is usually associated with the onset of any acute febrile illness Nevertheless the respiratory symptoms are so well marked and the patient's complaint is so entirely referred to his chest that one is, we think, justified in separating out a definite clinical group—the bronchitic

The pneumonic and broncho-pneumonic type —The term pneumonic is not strictly accurate for the whole of this group of cases, and all that it is meant to convey is that we are dealing here with a group of cases in which the physical signs suggest that there are in the lungs areas of more or less extensive consolidation, some definitely lobar, others lobular or confluent lobular To this group belong the fatal cases already referred to. In all of these seven cases subtertian parasites were demonstrated in the blood and in all were definite physical signs, in some lobar, in others lobular consolidation. Of these seven cases at autopsy four showed definite lobar consolidation of one or more lobes, complicated in two cases by hæmorrhagic pleurisy. These showed the ordinary macroscopic appearance of lobar pneumonia in the grey hepatic stage. In the other three cases there was extensive lobular consolidation of both lungs. In one case there was present in addition to the broncho-pneumonia, 12 ounces of blood stained serous fluid in the pleural cavity. In both these groups we would appear to be dealing with a superadded infection in which the malarial parasite was at the most but a predisposing cause. It is worthy of note however, that during this period only one case of pneumonia unassociated with malaria was admitted.

A third group comprised a series of cases which from the onset of the illness presented definite pulmonary physical signs and symptoms which pointed to areas of definite consolidation in the lungs, though the course of the disease was not that of a true lobar or lobular pneumonia. Two cases are described in detail. In both subtertian parasites were demonstrated in the blood.

Private F, aged 20 reported sick on Oct. 22nd, 1916 complaining of shivering, malaise and diarrhœa. Admitted to hospital on the 29th. He was pale, with slight icteric tint of sclerotics. The spleen was three fingers breadth below costal margin. Over left lower lobe posteriorly there was evidence of consolidation with bronchial breathing and numerous medium sized moist râles. Anteriorly there was bronchial breathing in second, third, and fourth left intercostal spaces. No definite dullness on percussion either anteriorly or posteriorly and vocal resonance and fremitus not markedly increased. The lung condition remained practically unchanged until Nov 13th, when the breath sounds lost their bronchial quality, became a little weak, and a friction rub developed over the left lower lobe posteriorly. On day of admission temperature rose to 103° F, pulse to 112, and respirations to 32. Next day temperature did not rise above 99°, but on following day again rose to 103°. It fell again on the subsequent day and then remained normal. The pulse-respiration ratio was not at any time much disturbed. There was little cough and no expectoration. He was treated with 20 grains of quinine intramuscularly twice a day for the first six days and then by 20 grains intramuscularly and 40 grains by mouth for the next seven days.

Lance-Corporal L. aged 29, reported sick on Nov 1st, 1916 complaining of pain in chest, headache, and shortness of breath, no shivering. On the 4th he was admitted to hospital with diagnosis of congestion of lungs. He did not have the general appearance of pneumonia nor did he look very ill. Dyspnœa was evident only on exertion. Spleen just palpable. Whole of right lung was involved. Anteriorly breath sounds above and below clavicle were bronchial and all over anterior aspect of lung were numerous moist sticky râles. Movement was diminished but no appreciable percussion dullness. Posteriorly there was slight percussion dullness over right supraspinous fossa and over right base. Breath sounds over supraspinous fossa were bronchial and in a small area just below spine of scapula distinctly tubular. Numerous râles were present all over right lung and a few râles at left base. On admission temperature 99·8° F, pulse 96 respirations 36. On following day temperature was again 99·8°, falling on third day to normal. On the fourth day his general condition became worse. The temperature rose to 102·8° and for two days he lay in a curious state of wandering delirium. His temperature fell on the following day and did not rise above 99° at any other period of his illness. During the sudden rise in temperature the pulse was 84 and respirations 30 showing a distinct disturbance of pulse-respiration ratio. The signs over right side of chest gradually diminished but on the 12th without any rise of temperature or any increase in symptoms a large area of consolidation was found over the left lower lobe posteriorly accompanied by numerous moist râles. On the 27th the right lung was completely clear but the left lower lobe still showed bronchial breathing and râles. At no time was there any expectoration. Treatment was carried out with quinine by mouth.

These cases have been detailed because, although the chest signs and symptoms were perfectly well defined suggesting a lobular consolidation the course of the disease was certainly not that of lobular pneumonia. One of the cases showed a disturbance of the pulse respiration ratio, the other did not. Neither case had any expectoration. In neither case was the temperature chart that of a pneumonia, but was certainly characteristic of a malarial attack. In both cases subtertian parasites were found in the blood. The character of the pulse remained good throughout the course of the disease, and at no time were the patients seriously ill. It is difficult to suggest what the exact pathological condition in those cases is, but we consider there is no doubt that there is a clinical type of malaria associated with the physical signs of more or less extensive consolidation of the lungs in which there is no evidence whatever of a superadded infection. This type may be conveniently designated the pneumonic.

Cerebral cases.—An extremely interesting, but relatively small, group of cases presented cerebral symptoms of the well recognised cerebral types, but, as we intend to describe these later in detail from the point of view of treatment, we will only briefly mention them here. In all we have had nine cases in which the dominant symptoms have been due to local affections of the nervous system. Two of these were of the bulbar type and showed temporary paralysis of the muscles supplied by the bulbar nuclei, both recovered and were discharged from the hospital without any evidence of organic disease. One patient was admitted with a diagnosis of debility. Twenty-four hours after admission he suddenly became comatose and remained so for 15 hours. He also completely recovered. One patient 21 hours after admission while in the latrine developed an epileptiform fit. These fits, which were of a general epileptiform character, were repeated about 12 times in the following 24 hours. The left leg became somewhat weaker than the right and developed an extensor plantar reflex, which at the time of writing is still present. In addition the patient still presents definite nystagmus and a tendency to a reeling gait, but no evidence of active disease. In four cases the most marked symptom was violent delirium which persisted for several days uninfluenced by variations in the temperature. In three of the cases there was a high, intermittent pyrexia, in one the temperature was never above 99° F. In all the cases subtertian parasites were demonstrated in the blood and all the cases completely recovered. One patient presented meningitic symptoms associated with pneumonia at the right base. This patient died. The autopsy showed a considerable excess of cerebro-spinal fluid beneath the tentorium with œdema of the pia arachnoid over the base, and congestion of the vessels over the pons. Section of the brain after hardening in formalin showed no evidence of gross brain disease. The middle and lower lobes of the right lung presented the features of an ordinary croupous pneumonia.

Generalised œdema with ascites.—Two cases were admitted complaining of breathlessness and having generalised œdema.

Driver W, aged 35 reported sick on Oct 6th, 1916 complaining of breathlessness swelling of feet legs, and face, and headache. Admitted to hospital on the 9th. On admission there was considerable œdema of hands, feet, and legs, and eyelids were puffy. Visible mucous membrane almost colourless, some lemon-coloured tinting of sclerotics. Abdomen notably distended, subcutaneous tissues œdematous, and all the characteristic signs of a considerable accumulation of free fluid in peritoneal cavity. The spleen extended almost to umbilicus, liver not enlarged. Slight mitral systolic murmur, rate of pulse 78 and rhythm of heart normal. Apex beat in fourth space in nipple line. Nothing abnormal was made out in the lungs. The urine was of a specific gravity 1012, clear, straw-coloured, no albumin, bile, or sugar, deposit showed a few uric acid crystals, but no casts. Temperature normal on day of admission (Oct 9th) but rose to 103° F on evening of 10th, to fall on morning of 11th to 99·8°. From the 15th onwards temperature remained normal. Blood film showed presence of subtertian rings and crescents. Treatment by intravenous quinine was commenced on the 10th and later continued intramuscularly and by mouth. On the 12th condition was immensely improved. œdema of feet and hands had almost disappeared and it was no longer possible to demonstrate free fluid in abdominal cavity. On the 16th the blood was free from parasites and he was discharged to hospital ship on the 23rd.

Private B aged 25 reported sick on Oct 27th, 1916 complaining of swelling of legs and breathlessness. Previous to present illness had always been healthy. He was admitted to hospital on the 27th. On admission patient presented notable œdema of legs and of subcutaneous tissues of back and abdomen and eyes were puffy. Visible mucous membrane pale, slight lemon tint of sclerotics. Abdomen considerably distended and gave all the characteristic signs of free fluid in abdominal cavity Spleen extended almost to umbilicus, lower margin of liver half an inch below costal margin Apex beat of heart in fifth space almost in nipple line, pulse-rate 96, rhythm normal, second pulmonic sound not definitely accentuated Nothing abnormal made out in lungs The urine did not contain albumin or casts Blood film showed presence of subtertian crescents and rings and red blood cells marked anisocytosis and polychromatophilia Temperature normal and remained so Patient treated at first with intramuscular quinine and later with quinine by mouth By Nov 11th œdema of extremities and physical signs of ascites had completely disappeared He was discharged to a hospital ship on Nov 15th

In these two cases we have the presence of œdema of the face and extremities and notable ascites without any evidence of either primary heart or renal disease Both cases showed the presence of subtertian parasites, and both very rapidly cleared up under quinine treatment Apart from the absence of any evidence of heart disease the distribution of the œdema, affecting the face, and the presence of a notable amount of ascites without enlargement of the liver are sufficient to exclude a cardiac origin for the œdema Similarly the presence of a perfectly normal urine in both cases excludes a renal origin We would suggest that the œdema is of toxic vascular origin similar to the œdema and ascites seen in the late stages of multilobular cirrhosis of the liver

Gangrene of the feet —Another group, consisting of three cases, showed evidence of local vascular changes in the development of gangrene of the toes

Private B, A.S C, aged 26, admitted to hospital on Oct 4th Reported sick on Oct 1st, complaining of loss of use of legs and numbness of feet He stated that he had not been unduly exposed before reporting sick On admission to hospital temperature was 102° F, conjunctivæ slightly icteric, and spleen palpable Blood film showed presence of numerous subtertian parasites He complained of very severe pain in both feet, shooting up the legs, both feet were considerably œdematous, and over dorsum of each foot was a large purple ecchymosis The great toe and all smaller toes of right foot and the small toes of left foot were slightly swollen and almost black in colour On soles of both feet from bases of toes backwards for a distance of about one inch the skin was purple in colour Sensation to gross touch was still present, the dorsalis pedis and posterior tibial arteries of both feet could be felt pulsating quite strongly As it was considered possible that a vascular spasm aggravated by quinine might be a factor in the condition, the patient was not given quinine, but was treated with 0 4 gm galyl intravenously Next morning the temperature had fallen to normal, and remained so for the remainder of the patient's stay in hospital The general condition steadily improved, blood reported negative to malaria on the 10th The feet rapidly improved, and apart from slight superficial necrosis on dorsum of right foot completely recovered On Oct 14th he was put on 20 grains quin sulph daily by mouth and was discharged to hospital ship on the 28th

Private M, aged 24, admitted to hospital on Oct 11th Reported sick on Oct 5th, complaining of shivering, pains in head and back For three weeks before reporting sick his company had been resting behind the line On Oct 7th when taking off his boots he noticed that his feet were cold and that his toes were blue He found that he was unable to stand on his feet on account of pain and because "he could not feel his feet" On admission to hospital his only complaint was pain in his feet Presented distinct icteric tinging of sclerotics, spleen palpable Both feet showed discolouration of the toes the left foot being more affected than the right All the toes of both feet were affected, the colour varying from brownish purple to purple On the left foot the plantar surface of all the toes showed small bullæ, on the right foot only the large and third toes presented bullæ The dorsalis pedis and the posterior tibial arteries of both feet could be readily felt pulsating Patient was put on 1 drachm quin sulph daily and steadily improved Both feet recovered without any loss of tissue

Driver W, aged 21, admitted to hospital on Oct 9th with diagnosis of malaria Reported sick about ten days before admission to base hospital on account of shivering and pain in head and back On second day of admission to a field ambulance the feet became very cold and continued so in spite of hot bottles Next day the feet were seen to be blue On admission to base hospital there was considerable œdema of both feet, all the toes of both feet were blue with large bullæ, especially on right big and second toes, extending for some distance over dorsum of feet Several bullæ were burst and were discharging sero purulent fluid The dorsalis pedis and posterior tibial arteries could be felt beating quite strongly in both feet Marked icteric tinging of sclerotics, spleen palpable one inch below left costal margin Blood film showed no malarial parasites Patient on admission was given an intravenous injection of 0 4 gm galyl, and ten days later was put upon quinine General condition rapidly improved, but considerable sloughing occurred over dorsum of large and second toes of right foot, involving loss of nail of great toe, and opening into first interphalangeal joint of second toe Also slight superficial sloughing over dorsum of left large toe

Mortality and Post mortem Findings

Thirty cases infected with malaria have died Of these one was a case of subtertian malaria who was quite convalescent from malaria when he developed an extremely septic throat followed by pneumonia Post mortem there was ulceration of the pharynx and epiglottis with septic consolidation of both lower lobes of the lungs In two cases there was in addition to malaria a Shiga dysentery and the patients died of running dysentery Post mortem, in both cases almost the entire mucous membrane of the whole of the lower bowel and the lowest two feet of the ileum was destroyed One case died of amœbic dysentery and septicæmia The mucous membrane of the lower bowel was much destroyed and there were abscesses in both kidneys Four cases died of lobar pneumonia affecting one or more lobes In one of those there was, in addition, an extensive hæmorrhagic pleural exudate In those cases malaria was not the cause of death

This leaves 22 cases with a total case mortality of 0 61 per cent Three cases presented at the autopsy extensive lobular consolidation of the lungs, complicated in one by hæmorrhagic pleurisy The immediate cause of death in those cases was also probably the lung condition, and it is a debatable question whether they respresent a double infection or a true complication of malaria Two cases died of septicæmia One was admitted to hospital with a septic arm following an intramuscular injection of quinine At the autopsy pyæmic abscesses were found in the lungs and kidney and recent vegetation on the mitral valve One was admitted in an extremely collapsed condition with numerous septic sores on both arms and developed signs of pleural and peritoneal effusion At the autopsy there was found a right-sided septic pleural effusion and septic peritonitis *Streptococci* were recovered from the pleural and peritoneal fluids

Excluding those 5 cases, we have 17 cases of uncomplicated malaria with a mortality of 0 47 per cent In one case the autopsy disclosed moderately advanced granular kidneys and in one case a right-sided hydronephrosis which had largely destroyed the right kidney

We take this opportunity of thanking Colonel Purves Stewart, C B, A M S, consulting physician to the Salonika Force, for his valuable assistance and advice, which was always at our disposal during this period To Lieutenant-Colonel P Mitchell we are also indebted for permission to use the hospital records, and to Captain R Richards, R A M C T F for the hæmatological and bacteriological and post-mortem reports

---

SHORTAGE OF MIDWIVES IN CORNWALL —At the last meeting of the Cornwall Sanitary Committee the county medical officer of health (Dr E M Clarke) reported that 20 additional midwives were required for the parishes of Cornwall He stated that at present there was an excessive birth mortality in the county, 4 5 per 1000 births, compared with 4 0 per 1000 in England and Wales, and 2 0 per 1000 in some London districts, adding that the mortality rate depended upon the quality and amount of attendance available at birth The committee decided to recommend the Cornwall County Council to make an additional grant of £275 for the training of nurse midwives

THE LATE MR ALFRED UPTON —The death occurred at his residence at Hove, on April 10th, of Mr Alfred Upton, L R C P Lond, M R C S, who had practised in Brighton and district since the year 1877 He came of an old North Sussex family, being a son of the late Mr Henry Upton, of Petworth Educated privately, he studied at St Bartholomew's Hospital, London, where he was Foster prizeman and obtained distinction in surgery and forensic medicine In 1875 he took the L S A diploma and became M R C S in the following year At Hove he had an extensive practice, and he will be greatly missed among the poorer classes, by whom he was regarded as a friend Mr Upton was a prominent Freemason, and was interested in sailing, cycling, and gardening He leaves a widow and daughter

NOTES ON THE SYMPTOMATOLOGY OF PARATYPHOID FEVER

BY J M FORTESCUE-BRICKDALE, M A , D M OXON , M R C P LOND ,
CAPTAIN R.A.M C (T F)

THE following notes on the symptomatology of paratyphoid fever are based on the study of the case sheets of patients admitted to an isolation hospital in France during the last five months of 1915 and observed by the writer and his colleagues The diagnosis was confirmed, or rather established, by laboratory tests in all cases, the routine examination including one or more cultivations from the blood, three or more cultivations from the urine and fæces, and three agglutination tests The large majority of the cases were infected by the *Bacillus paratyphosus B*, the incidence of typhoid and paratyphoid A being so small that these infections have not been included in the tables given below, which refer solely to 237 available records of paratyphoid B

The main features to which attention will be directed are (1) The type and symptoms of onset, (2) the type of pyrexia, (3) the condition of the spleen, (4) the eruption, (5) the appearance of the patient and the general course of the disease These points do not, of course, by any means cover the whole ground, but may be found of some interest to those who desire to study the clinical details of the enteric group of infectious fevers

1. *Type of onset* —Three types have been noted —

(*a*) The abrupt onset, which is by far the most frequent in this series, and includes two thirds of the cases The history of this type of case begins with an abrupt rise of temperature, accompanied by headache, shivering, and general malaise Diarrhœa, usually lasting a few days, is common, and less so abdominal pain and vomiting The initial diarrhœa occurs more frequently in cases in which the febrile attack is prolonged, and the same is true of vomiting Thus in 56 cases in which the fever lasted for more than 14 days, initial diarrhœa occurred in 52 per cent In 34 cases in which the fever lasted for 7 to 14 days it occurred in 30 per cent, while in 18 cases of under one week's fever the percentage was only 22

(*b*) The second type of onset is still sudden, but is preceded by a variable prodromal period in which the patient is not well, but is generally able to perform his usual duties This type was noted in 16 per cent of the cases The prodromal period varied in length, in one case it was given as 12 hours, and in others as two or three weeks, but usually it lasted for two or three days The most usual symptom during this time was diarrhœa, which was noted in 36 per cent of the cases, headache occurred in 20 per cent, anorexia in 12 per cent, backache and abdominal pain in 8 per cent The abrupt exacerbation or true onset did not differ from that described above

(*c*) The third type only occurred in 16 per cent and was gradual and prolonged It differed from the other two groups, as will be seen from the following figures —

	Per cent		Per cent
Gradually increasing headache	83	Mild diarrhœa	42
Abdominal pain	50	General aching	33
		Vomiting	21

The point at which the patient gave up work was variable, and did not depend entirely on the severity of the symptoms, so that an actual day of onset was difficult to fix

Some relationship appears to exist between these three types of onset and the duration of the fever, or, in other words the severity of the intoxication In the following table it will be seen that the abrupt onset though most frequent in all cases occurs in a higher proportion among the shorter attacks while the highest percentage of insidious onsets is found among cases of a more prolonged and severe character

Duration of fever	No of cases	Percentage with—		
		Sudden onset	Prodromal symptoms	Gradual onset.
Over 14 days	90	62·2	20·0	17·8
7 to 14 days...	45	75·5	11·1	13·3
Under 7 days	22	81·7	9·1	9·1

Symptoms of onset —The following table shows the frequency of the various *initial* symptoms and is based on the records of 157 cases It is interesting to note that this table corresponds very closely with the figures published by Torrens and Whittington,[1] and Wiltshire [2]

	Per cent.		Per cent
Headache	84	Cough	13
Shivering	49	Vertigo	11
Diarrhœa	41	Constipation	7
Abdominal pain	32	Sore-throat	3
Backache	28	Epistaxis	2
Vomiting	25	Herpes labialis	1
General aching	24	Fainting	1

If the three tables are combined the following results are obtained —

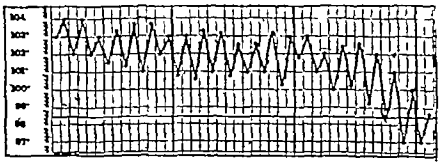
Headache	90%	out of 385 cases	General aching ..	25%	out of 385 cases
Diarrhœa	45%	385	Vomiting ..	17%	335
Shivering	37%	307	Cough	13%	307
Abdominal pain	32%	385	Epistaxis	10%	307
Backache	26%	307	Vertigo	9%	307
			Sore-throat	4%	385

2 *Type of pyrexia* —The longer fevers naturally show a more characteristic type, thus in 97 cases in which the pyrexia was maintained for 10 days or more the following five types were distinguishable —

(1) *Simple continued type* —These constitute about 29 per cent of the total and show no distinctive features except the common tendency to remission towards the end of the attack (Chart A) In the chart shown the course of the fever is remarkably regular, and shows the abrupt initial rise In other cases in this group the temperature was more fluctuating and irregular

CHART A (Type 1)

The chart gives in each case the morning and evening temperature, and the thicker lines indicate intervals of a week



(2) *Intermittent type* —This group includes 43 per cent of the series, and is to a certain extent characteristic of paratyphoid infections The temperature in these cases, while remaining high in the evening, drops towards or below normal in the morning ("spiky chart") The intermissions may be observed either at the beginning or end of the attack (Chart B), but are probably most frequent when the temperature is beginning to fall (Charts C and D)

CHART B (Type 2)

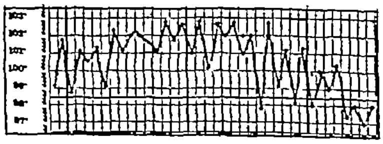


CHART C (Type 2)

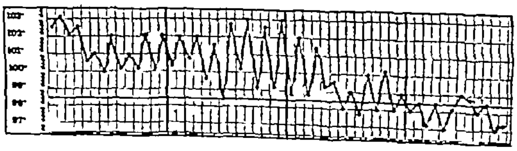

CHART D (Type 2)

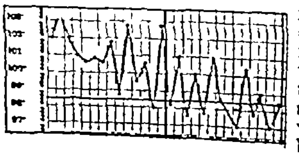


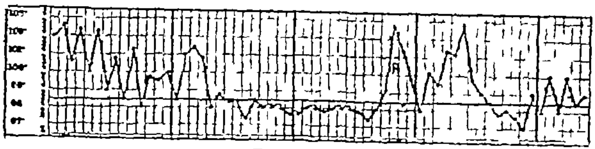
(3) *Undulant type* — This small group constitutes 12 per cent of the cases No correlation was traced between this type of temperature and other features in the attack either as regards severity, the appearance of the rose spots, or the agglutination reaction of the serum The mean duration of the fever was

---

[1] Brit. Med Jour Nov 13th 1915
[2] Practitioner, 1915

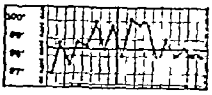
22 days, the longest period being 34 days and the shortest 14 In one case (Chart H) a relapse occurred showing the same type of temperature as did the original attack

CHART H (Type 3)



R relapse

CHART H (continuation)



In two cases the rise of temperature constituting the ascending wave was definitely due to pleurisy and bronchitis and in five others there were physical signs of bronchitis in the lungs, but no correspondence could be traced between the undulations in the temperature and the extent of the bronchial affection In two cases not included in this group the temperature rose again after an apyrexial period of one or two days, which seems to connect the undulant type with attacks, followed by a definite relapse

(4) *Low irregular fever* —In 5 per cent of the series the fever was a low, irregular type, the morning temperature being normal or subnormal and the evening temperature usually 99° or 100° F This type may begin with a few days' high fever The mean duration of the pyrexia in this group was 33 days, the longest period being 63 days and the shortest 15 days The illness, though somewhat prolonged, is, as might be expected, of a mild nature It is not associated with any special clinical or bacteriological characteristics (Chart L)

CHART L (Type 4)

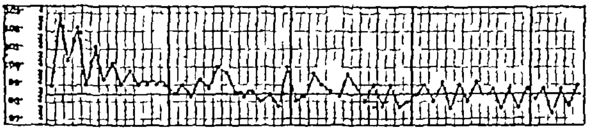


CHART L (continuation)

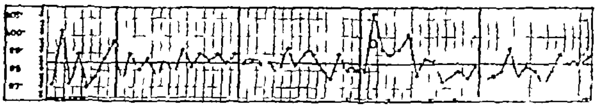

O otitis media

(5) *Type with subsequent rises of temperature* —In this group, about 11 per cent of the total cases, the initial fever may present the characteristics of any of the preceding types, the outstanding feature of the group being a sudden rise of temperature lasting from 24 to 48 hours, which occurs some days after the primary pyrexia is over and the general symptoms have subsided These sudden rises may be repeated at intervals, they are usually accompanied by some headache and the general aching pains common in febrile states, but all the symptoms clear up as soon as the temperature becomes normal In one case severe sweating and shivering were noted, in one case the spleen was enlarged, and in two there was tenderness over the left hypochondrium In none of these cases was tenderness over the gall bladder noted, though this occurs and has been held to point to a cholecystitis In one case a blood culture made when the temperature was rising showed a negative result In true relapse a positive culture can often be obtained from the blood when the temperature rises abruptly on the first or second day (Charts M and N)

CHART M (Type 5)

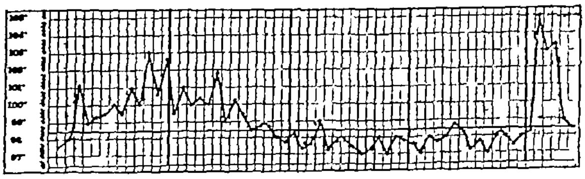

CHART N (Type 5)

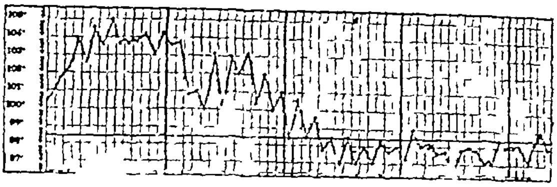

CHART N (continuation)

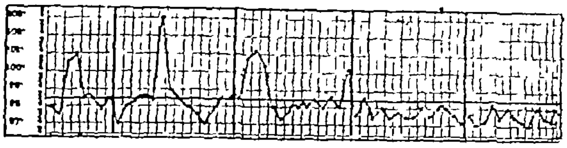
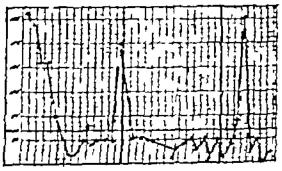


The following table shows the days on which the temperature rose in 11 *cases, reckoned from the first day of normal* temperature

7th day	1 case	5th and 12th day	1 case
8th	3 cases	9th and 15th day	1 case.
16th	1 case	15th and 20th day	1 case.
17th	1 case	25th and 31st day ..	1 case.
4th and 9th day	1 case.		

In another series of 31 cases in which the fever lasted for 10 days or less the same phenomenon was observed in 4 cases Two of subsequent rises of temperature occurred on the sixth day after the subsidence of the initial fever, one on the thirteenth day and one on the twenty first day In a fifth case, in which the initial fever was very short, the subsequent rises occurred on the fifth and fourteenth days In this case the agglutinations were positive to paratyphoid B on two occasions in dilutions of 1 750 and 1 500 respectively, but no cultures were obtained (Chart O)

CHART O



3 *Condition of the spleen* —In the total series of cases the spleen could be palpated in 43 per cent, increase of splenic dullness and tenderness in the splenic region were observed in others in which the organ itself was not felt

In a few cases the spleen was palpable as early as the fourth day of disease, and in most it remained so till the end of the febrile period Occasionally it did not return to its normal size for two or three days after the temperature had fallen *In these cases no relapse occurred* The organ is firm to the touch and the edge is usually easy to delimit, in six necropsies the actual weight varied from 3½ to 9 ounces, the average being 6½ ounces

4 *The eruption* —The characteristic eruption was observed in 63 per cent of the total series

The earliest appearance of the rash (one case) was on the third day and in some others it appeared for the first time on the fourth In some cases crops of spots continued to come out till the beginning of the fifth week, and the last appearance of spots was in not a few cases subsequent to the final fall of temperature The most marked feature of the rash was its pleomorphism, the following types occurring either singly or in association on the same patient —

(i) Small, well-defined spots, not much raised and of a darkish pink colour

(ii) Large, well raised, light pink spots, with ill defined, irregular margins

(iii) Fairly well defined spots surrounded by a faint pink or purplish areola

(iv) Moderately sized, well-defined spots, conical in shape, with a tendency to become vesicular

5 In the milder cases the appearance of the patient is *not distinctive but in cases of more* severe type there is a peculiar bloated, flushed appearance which is to some extent characteristic The patient is also somnolent or drowsy, but as a rule can answer questions accurately when roused. Although intensely toxic cases occur, in the great majority the patient does not appear so poisoned as the height and duration of the fever would lead one to expect Convalescence *is soon* established, and if no sequelæ occur complete re-establishment of health is rapidly attained A brief period of tachycardia *is not, however,* uncommon during convalescence In three fifths of the cases summarised the fever lasted for more than 14 days

AN IMPROVED METHOD FOR THE ESTIMATION OF SUGAR IN THE URINE AND BLOOD

BY P J CAMMIDGE, M D LOND

IN the *Journal of Biological Chemistry* for November, 1915[1] F M Scales described a new volumetric method for estimating reducing sugars, which he states gives as accurate results as those obtained by weighing, but with an expenditure of less than a quarter of the time

A known volume of the saccharine solution is added to an excess of Fehling's solution and the mixture boiled for two minutes. It is then agitated to bring the precipitated cuprous oxide into suspension immediately poured through a special funnel into dilute hydrochloric acid contained in a specially prepared volumetric flask, and made up to the mark with boiling water After thorough mixing an aliquot part of the resulting cuprous chloride solution is pipetted into a known volume of dilute standard iodine solution and the iodine not reduced by the cuprous chloride titrated with a standard solution of thiosulphate, using dilute starch as the indicator The difference between the number of cubic centimetres of thiosulphate solution oxidised by a blank control containing the same volume of iodine solution and the number of cubic centimetres of thiosulphate acted on by the iodine remaining after the addition of the cuprous chloride being proportional to the amount of cuprous oxide in the original solution, and this in its turn depending upon the strength of the saccharine solution, the percentage of sugar in the latter can be calculated by the use of appropriate tables and factors

Shortly after the appearance of Scales's paper I carried out a number of experiments with solutions of various reducing sugars of different strengths, and was able to confirm his claims as to the accuracy and speed of the process I therefore decided to adapt it to the estimation of sugar in the urine, as it did not involve the use of chemicals that are now difficult to obtain or are prohibitive in price, beside being simple and comparatively rapid. Experience suggested modifications in the technique to overcome minor difficulties which were encountered and resulted in the evolution of a process that is, I think, an improvement on Scales's method An account of the procedure I now employ may be useful to others, especially as, with slight modifications, it can be used for the estimation of sugar in the blood, cerebro spinal fluid, &c , thus avoiding a multiplicity of apparatus and reagents, and giving results that are more strictly comparable

In place of the Fehling solution employed by Scales I use a modified Benedict solution, made by dissolving 200 gm of sodium citrate 100 gm of anhydrous (or 200 gm of crystallised) sodium carbonate and 10 gm of sodium bicarbonate in about 600 c c of distilled water by the aid of heat, and adding to it with constant stirring a solution consisting of 21 gm of crystallised copper sulphate dissolved in about 150 c c of distilled water When the mixture has cooled to the room temperature it is made up to 1000 c c with distilled water and filtered Preserved in a tightly stoppered bottle, this solution keeps indefinitely and may be used for qualitative as well as for quantitative work It is about ten times as sensitive to the reducing action of sugar as Fehling's solution so that a very small proportion of urine gives an unmistakable reaction even when it contains a very low percentage of sugar, and as it is not appreciably reduced by uric acid, creatinine, &c , the main difficulties encountered in using Fehling's solution are obviated

Owing to the presence of sodium carbonate the addition of hydrochloric acid in the quantitative method causes an evolution of carbon dioxide, so that the subsequent operations are carried out in an atmosphere of that gas, thus preventing oxidation of the cuprous salts by the air—an improvement on Scales's process where reliance is placed on the high temperature, speed of manipulation, &c I find that the best results are obtained if 25 per cent of a saturated solution of sodium carbonate (20 per cent) is added to the copper reagent immediately before use One of the drawbacks to Scales's original method is the way the reduced cuprous oxide tends to adhere to the walls of the beaker, especially after it has been used for several estimations and if it is not of Jena glass By adding the hydrochloric acid to the boiling copper solution this difficulty is overcome and, as the atmosphere of steam in the beaker is replaced by inert carbon dioxide, the risk of oxidation is diminished The cuprous chloride solution that results still in its atmosphere of carbon dioxide, may be poured directly into the iodine solution through a suitable funnel without coming in contact with the air, at the same time avoiding the discomfort of measuring and pipetting the boiling hot liquid The omission of the latter processes is also an economy of time

Twentieth normal iodine solution is the most convenient to use As the accuracy of the results depends largely on this solution, it must be very carefully prepared by dissolving 9 gm of potassium iodide in about 200 c c of distilled water then adding exactly 6 35 gm of pure re-sublimed iodine and shaking occasionally until it is dissolved, finally, the solution is made up to 1000 c c with distilled water A corresponding twentieth normal solution of sodium thiosulphate is made by dissolving about 13 gm. of the crystallised salt in about 500 c c of distilled water and making up to 1000 c c This solution is standardised against the iodine solution, preferably after standing over night, using a 1 per cent starch solution as the indicator and diluting as necessary according to the formula, $\frac{N \times d}{n} = C$, where N = the quantity of thiosulphate solution left to be diluted (in cubic centimetres), d = the difference between the actual and theoretical number of cubic centimetres of thiosulphate required in the trial, n = the number of cubic centimetres actually used, and C = the amount of distilled water (in centimetres) to be added to bring the solution to the standard strength

The only special apparatus required in carrying out an estimation is a 200 c c conical flask fitted with a rubber stopper perforated with two holes, through one of which is passed the stem of a large headed thistle-funnel, while the other is left open to act as a vent The stem of the funnel is drawn out to a jet and is so arranged that the tip of the jet is just covered when the flask contains 100 c c of water

Detection of Sugar in the Urine

The modified Benedict solution is first used to determine the presence of a pathological excess of sugar in the urine and also to gain an approximate idea of the amount

For this purpose about 5 c c of the solution are placed in a clean test-tube and eight drops, not more, of the urine added The contents of the tube are then boiled, either in a free flame for one to two minutes, or, what I find much better, in a boiling water bath for five minutes In the latter case the water must be actively boiling when the test-tube is placed in the bath and it must be kept in a state of active ebullition for the whole of the five minutes The advantages of this method are, first, the tendency of the boiling fluid to bump and spurt is avoided, second, there is no appreciable loss by evaporation, which may cause a misleading turbidity, third, a number of tests may be carried out simultaneously in a numbered rack, thus saving time

When the heating is completed the test tube is allowed to cool undisturbed at the room temperature for two minutes, if the urine is "sugar free" the copper solution is clear, or only shows a faint blue turbidity due to precipitated urates, at the end of that time, should sugar be present, it becomes more or less opaque and changes colour either before or after cooling the bulk, colour, and rapidity of formation of the precipitate varying with the percentage of sugar If there is only a small amount, under 0 1 per cent , or the reducing substance is chiefly pseudo lævulose,[2] a light green opacity forms after the test tube has been removed from the water bath , a more bulky green precipitate, present when the tube is taken out of the boiling water, indicates about 0 1 to 0 5 per cent , a dense yellow precipitate suggests about 0 5 to 2·0 per cent , and a thick red precipitate points to there being over 2·0 per cent of sugar

Estimation of Sugar in the Urine

When a rough idea of the probable percentage of sugar has been gained a specimen of the urine is diluted with water according to the following scheme —

A, light green precipitate	dilute 40 c.c	to 100 c.c
B a dense yellow	” 20	”
C a thick red	” 10	”
D occasionally*	” 5	”

(* This dilution is only required if the urine contains over 6 per cent of sugar which is shown by a trial estimation with the previous dilution failing to give a satisfactory result.)

Exactly 5 c.c of the diluted urine are now added to 15 c c of modified Benedict solution and 5 c.c. of a saturated solution of sodium carbonate, contained in a 200 c c beaker The beaker is covered with a watch glass, placed on a wire gauze over the flame of a Bunsen burner, and its contents heated to boiling After exactly three minutes' boiling the watch glass is removed and 10 c.c of hydrochloric acid (sp gr 1 16) are cautiously run in, taking care to avoid excessive frothing The contents of the beaker are now poured as rapidly as possible into the thistle funnel of the flask *described above*, which has been previously prepared by placing in it about 100 c c of water and exactly 20 c c of *twentieth normal iodine solution*, measured with a pipette kept for the purpose Care must be taken that the copper solution does not run into the flask too quickly and that it is thoroughly mixed with the iodine solution, as it does so by gently rotating the flask The beaker is washed out with a few cubic centimetres of hot water and the washings poured into the funnel

---

[1] Jour of Biol Chem. 1915 xxiii., 81

[2] Cammidge: THE LANCET, 1915, i. 320 1916, i , 1216

The flask is now unstoppered, the stem of the funnel washed into the iodine with a little water, and the standardised *twentieth normal thiosulphate* solution run into the latter from a burette until the brown colour of the iodine is almost discharged At this point five or six drops of fresh cold starch solution (about 1 per cent) are introduced and the addition of the thiosulphate continued until the blue colour of the resulting iodo starch is completely discharged When the end point is reached the solution has a faint light green colour which it is quite easy to distinguish from the blue of the iodo starch, even by artificial light A control consisting of 100 c c of water and 20 c c of twentieth normal iodine, measured with the same pipette is titrated with the *sodium thiosulphate* solution in a similar way The difference between the number of cubic centimetres of thiosulphate used in the test and consumed by the control, multiplied by a factor varying with the dilution of the urine employed according to the following table, gives the percentage of sugar in the original urine —

If a 40/ dilution	(A)	*was used, multiply by*	0·0845
20/	(B)	,	(2 × 0 0845) = 0 169
, 10/	(C)		(4 × 0·0845) = 0 338
5/	(D)		(8 × 0 0845) = 0 676

The total excretion for the day can then be worked out if *the amount of urine passed is known This is essential* if reliable inferences are to be drawn, for although it seems obvious that a consideration of the percentage of sugar or any other substance alone is likely to be misleading, especially in a condition where the daily output of urine may vary considerably from the normal *average, it is a fact that* is frequently overlooked, as patients are often sent to me for consultation bringing an odd sample of urine, either *not* taken from a 24 hour collection, or, *if it is*, without any attempt having been made to estimate the quantity passed

With the apparatus and solutions at hand an accurate determination of the percentage of sugar in a urine may be made by this method in ten minutes or less, and when a *series of estimations is being carried out* the time for each can be still further reduced A control for every specimen is not necessary, but as the sodium thiosulphate solution gradually deteriorates on keeping, especially if it is not prepared with fresh distilled water and is not kept from contact with the air, *it should be titrated against* the standard iodine at frequent intervals When it is used only occasionally it would probably be best to keep a stock solution of approximately double strength and dilute down as required, according to the results obtained with a trial titration against the standard iodine solution

Estimation of Sugar in the Blood

The same reagents and apparatus are employed as for the determination of sugar in the urine, but the iodine and thiosulphate *solutions are diluted* with distilled water, in a measuring flask, 1 in 50 (i e , to thousandth normal), and it is an advantage to use a smaller beaker (50 c c) and a smaller flask (100 c c) and funnel for the iodine As the dilute solutions do not keep well they should be prepared *fresh as required*

For most cases of glycosuria and for normal persons 0 2 c c of blood is used but *when a very high blood sugar is* expected (over 0 35 per cent) only 0 1 c c should be taken *These quantities may be readily obtained* from a prick with a needle, especially if the thin and comparatively insensitive skin at the root of the finger nail is selected and the finger is congested by swinging the warm hand in a dependent position for a few moments and then constricting the finger with a narrow bandage or rubber tube It is hardly necessary to point out that an accurately graduated pipette of *narrow* bore should be used for measuring the blood, and that any excess adhering to the outside must be carefully wiped *off* when the required quantity has been drawn up into the pipette In order to remove the albumin from the blood and secure a *solution* suitable for sugar estimation, it is laked by mixing it with a known volume of deci normal acetic acid *(1 c c of glacial* acetic acid to 125 c c of distilled water) made up to a definite volume with a saturated solution of sodium chloride, boiled, cooled and filtered An aliquot part of the clear filtrate is employed *for the sugar* estimation

The details of the method are as follows —

Exactly 3 c c of deci normal acetic acid are placed in a clean test tube and 0 2 (or 0 1) c c of blood is added, the pipette being washed out with the acetic acid two or three times by suction The mixture is allowed to stand for at least five minutes and subsequently made up to 10 c c by adding exactly 6 8 c c (or 6 9 c c if 0 1 c c of blood was used) of clear saturated sodium chloride solution The test-tube is now placed in a bath of boiling water *for a minute or two*, then cooled in running water, and its contents poured on to a small dry filter paper (5 5 *cm diameter*) As the clot is apt to slide out of the tube suddenly and cause the solution to overflow the filter it should be broken up previously by tapping the tube against the finger The first few drops of the filtrate are generally turbid and should be returned, as an absolutely clear filtrate is required

When a sufficient amount has come through exactly 7 5 c c are measured with a pipette into a small beaker containing 1 c c of modified Benedict solution and 1 c c of saturated sodium carbonate solution The beaker is covered with a watch glass, placed on a wire gauze over a Bunsen flame, and its contents gently boiled for exactly three minutes The flame is then removed and 2 c c of pure hydrochloric acid (sp gr 1 16) *are cautiously added* The solution is at once poured into a thistle funnel flask con*taining 25 c c of distilled water and 20 c c of thousandth* normal iodine solution, the same precautions as to mixing *&c , being taken as in the urinary sugar determination* The beaker is washed out with 2 or 3 c c of hot distilled water and the washings poured into the funnel The liquid adhering to the stem of the funnel having been washed into the flask with distilled water, the iodine is titrated with standardised thousandth normal sodium thiosulphate solution, using 3 drops of freshly prepared cold starch solution (about 1 per cent) as the indicator when the brown colour of the iodine has been almost discharged The end point is shown by the disappearance of the last faint trace of blue, or purple with a resulting colourless solution when the flask is examined against a dead white background by diffused daylight , artificial light does not give satisfactory results In warm weather *it is advisable to cool* the flask in running water before titration, as the last trace of blue is then more *readily seen*

A control titration with 25 c c of distilled water and 20 c c of thousandth *normal iodine is carried out for* each blood or consecutive series of bloods, and the end point carefully matched *The difference between the number of cubic* centimetres of thousandth normal thiosulphate used for the test and for the control multiplied by 0·0203 (or 0·0406 if only 0 1 c c of blood was used) gives the percentage of sugar in the blood The same method may be employed for determining the sugar content of cerebro spinal fluid, &c

These methods have been in daily use in my laboratory for over a year I find that they are *reliable* and are economical of time and material as compared with *others previously* employed The modified Benedict solution, which keeps *indefinitely unchanged, avoids most of* the fallacies of Fehling s solution and may be employed for both qualitative and quantitative work The end point of the urinary sugar determination is definite and easily recognised, even by artificial light, so that satisfactory results can be obtained *with very little practice and the whole process* is so simple that it can be readily learned The use of the same reagents and apparatus for the urine and *blood is a considerable* advantage from several points of view and not least that comparable data are secured As only a small amount of *blood is required for each* estimation several examinations of the same patient may be made on one day, if necessary, without discomfort *This is a matter of no* small importance since the sugar content of the blood is now recognised to be of greater value in the diagnosis and treatment of diabetes *than a determination* of the output of sugar in the urine

Nottingham place, W

DEATH OF MR JOHN KING —The death occurred *at his residence at Stratton, Cornwall*, on April 11th, of Mr John King, L R C P Edin , M R C S , L S A , J.P , in his 72nd year He belonged to an old Cornish family who have practised in Stratton for many generations He succeeded to his late father's practice nearly 50 years ago, and was for a long time medical officer of health for Stratton and Bude It is mainly to his efforts that those towns have an efficient sewerage scheme, and he worked hard to secure the excellent water supply which Bude now possesses He was a justice of the peace for Cornwall

ROYAL SOCIETY OF MEDICINE

SECTION OF ANÆSTHETICS

Anæsthetics at a Casualty Clearing Station

A MEETING of this section was held on Feb 2nd Mr **GEORGE ROWELL** the President, being in the chair

Captain **GEOFFREY MARSHALL**, R A.M.C, read a paper on Anæsthetics at a Casualty Clearing Station He showed that owing to the circumstances under which operations are performed at clearing stations the correct choice of anæsthetic often determines the patient's chance of recovery or the opposite He discussed the choice as it affects the lightly wounded, those seriously wounded, and those suffering from serious sepsis For the first class either gas and oxygen or an induction by warm ether and chloroform vapours was employed, warm ether being continued with He showed that an investigation of the blood was an all-important step towards securing the right anæsthetic for those suffering severely from recent wounds If there was a hæmoglobin percentage of less than 100, showing that the blood was dilute and that blood had been lost, then the use of stovaine by spinal injection was almost certain to be associated with serious fall of blood pressure and symptoms of collapse, and might lead to fatal results The blood *diminution* did not produce the same effect if 40 hours or more had passed since the infliction of the injury The conclusions as regards spinal analgesia were gathered mainly from consideration of 50 cases in which the hæmoglobin percentage blood pressure, and pulse rate were recorded before the injection of stovaine. Keeping the head low was found to be the most important step in preventing or combating collapse, and this position should be maintained *for an hour* after the return to bed Intramuscular pituitrin was found of little use and intravenous saline gave only *temporary help* Intravenous ether also did not give good results in the case of the shocked and recently wounded Captain Marshall found gas and oxygen the most satisfactory anæsthetic for wounds of the limbs of extreme severity and warm ether vapour for abdominal cases and for head cases For chest cases and mixed chest and abdominal cases warm chloroform vapour with oxygen proved the most satisfactory agent, in the latter instances it was best preceded by injections of morphia scopolamine and atropine Collapsed patients received intravenous saline towards the close of the operation

The paper was discussed by Colonel **HUGH RIGBY** who had seen much of the work on which Captain Marshall's paper was founded, by Mr **TYRRELL GRAY**, who disputed some of Captain Marshall's conclusions upon spinal analgesia and blood pressure, and by Mr **Z MENNELL**, Mr **H E G BOYLE**, and Mr **H BELLAMY GARDNER**

Sudden Death in Tabes Dorsalis —Limitations of Vaccine Treatment

A MEETING of this section was held on March 30th, Dr **H C DRURY** the President being in the chair

Dr **A R PARSONS** read a paper on two cases of Sudden Death in Tabes Dorsalis The first a man aged 41 had consulted him two years before complaining of some difficulty in walking and unsteadiness noticed chiefly while washing his face There was also slight trouble in micturition—at first difficulty in passing, later some loss of control Seventeen years previously he had a sore on the glans penis but no other symptoms His wife had had one miscarriage He was a healthy man with the exception of his nervous system which showed typical if rather slight signs of locomotor ataxia. Wassermann reaction was faintly positive The case ran the usual course for two years when one day at dinner the patient who during the day had been in his usual good general health, suddenly changed colour, and when examined was found to be dead The second case was similar, death occurring suddenly during a game of bridge In neither case could an autopsy be obtained, but frequent careful physical examination during life showed no evidence of arterial disease, and this could almost certainly be excluded He considered the most probable explanation of death to be "cardiac crisis," a condition almost entirely overlooked in text-books, but mentioned by a few authors, notably Gowers and Osler —In the discussion which followed the **PRESIDENT** thought that, in the absence of previous anginal symptoms, it was questionable whether death could fairly be ascribed to cardiac crisis In several cases of sudden death Professor P T O Sullivan had, he said, found as the only recognisable lesion a sclerotic or atheromatous condition of the aorta about the openings of the coronary arteries —Sir **J W MOORE** suggested that death was more probably due to brain mischief, e g, cerebral hæmorrhage —Dr **PARSONS**, in reply said that as far as was possible by clinical examination arterial disease had been excluded Death was, he thought, too sudden in both cases to be explained by cerebral hæmorrhage

Dr **R J ROWLETTE** read a note on the Limitations of Vaccine Treatment He spoke of the difficulty in general of judging of the value of a particular method of treatment, increased in the case of vaccines by the fact that treatment had been allowed to remain largely in the hands of men without clinical experience In preventive treatment, the case for vaccines was now admitted, particularly in view of the experience of the present war In curative treatment the efficiency of vaccines was limited by the power of reaction of the tissues Moreover, while vaccines could stimulate the tissues to resist an active infective process, they had no power to restore integrity of the tissues after infection had ceased Again, for vaccine treatment to be effective, accurate bacteriological diagnosis was a preliminary requisite There was no incompatibility between vaccine treatment and the employment of other therapeutic methods whether surgical or medical Knowledge of the principles of immunity and of the practice of inoculation should in future be part of the instruction in therapeutics given in the medical curriculum

Reviews and Notices of Books.

Organisation Physiologique du Travail By **JULES AMAR**, Docteur ès Sciences Directeur du Laboratoire des Recherches sur le Travail Professionnel au Conservatoire National des Arts et Métiers With 134 illustrations Paris H Dunod et E Pinat Pp 374 Price 18 fr

THIS volume represents part of the work which M Jules Amar has been carrying on at the Conservatoire National des Arts et Métiers at Paris since 1912 and for its full understanding requires to be read in conjunction with his book 'Le Moteur Humain et les Bases Scientifiques du Travail Professionnel" M Amar has been inspired by the work of Frederick Winslow Taylor, an American mechanical engineer, who from an artisan became a factory owner By effecting improvements in the tools and methods employed by his workmen the output of his works was very considerably increased

In his "Principles of the Scientific Organisation of Work" Taylor complains that the physiologist has not paid sufficient attention to "fatigue.' M Amar has now remedied this omission The volume contains a description of the various methods he employs to investigate "fatigue' The phenomena of the contraction of muscles are recorded by a dynamograph, the muscular force is conducted by a spring which presses on an indiarubber ball connected by tubing with a Marey's tambour provided with a writing style which registers on a revolving cylinder the amplitude of the movements of the muscles Dynamographs are fitted to various tools including the file plane and shovel, the force, rate and precision of the movements *involved* in their use can thus be *registered* The energy expended is determined from the consumption of oxygen during respiration, to measure this he uses a eudiometric apparatus attached to a respirator fitted over the workman's mouth Deductions are made from cardiograms and pneumograms, curves are made of the variations of pressure of the expired air, the ratio of the duration of expiration and inspiration affords useful data The ergometric (bi)cycle serves to measure the fatigue of the legs and arms, M Amar s modification of the Mosso chirograph is used to investigate the fatigue of the muscles moving the fingers or wrist, the *poire dynamographique* (a hollow indiarubber ball fitted with air, the pressure of which can be varied), measures the grasping power of the hand, the arthrodynamometer measures the amplitude of movements of joints and the force of the muscles producing the movement

In this book M Amar does not go closely into the application of his principles to each of the various trades, he contents himself with urging that the use of his registering tools will indicate to the workman various faults which should be overcome He emphasises the advantages of the correct position to assume when using a file, the cinematograph, he suggests, will indicate this position and help to eliminate any unnecessary actions during work But the author gives a complete account of the adaptation of his methods for the functional and professional re education of crippled soldiers, not only this, but he works out in a convincing manner the scientific principles of artificial limbs By means of his dynamographic platform he analyses the movements of artificial legs, and is able to indicate the models which most nearly allow of the reproduction of the normal movements during walking He gives a description of the various forms of artificial limbs he considers most useful both for the workshop and office An account of his *pince universelle, anneau universelle*, and hook is included He is an advocate for fitting elaborate mechanical hands even to men who have suffered an amputation at the shoulder, when the movements of the hand are produced by the expansion and retraction of the chest wall during breathing A wide difference of opinion exists in France as to the value of such elaborate appliances M Amar s results lends support to those in favour of them Possibly their provision is justified when limited to selected men of better education whose work is of a light nature and who are prepared and in a position to go to a certain amount of trouble to keep their appliances in order

The book is written for the French general public M Amar has therefore included matters of interest primarily to Frenchmen as well as elementary physiological considerations When dealing with general matters he is somewhat diffuse but no such fault can be found when he gives us in book form the papers he has written on his own work The book is the work of a pioneer and patriot, who is evidently gratified that the direction his life's work has taken has suddenly become of immediate value to the crippled defenders of his country

JOURNALS AND MAGAZINES.

Journal of Physiology Edited by J N LANGLEY Sc D, F R S Vol. LI, Nos 1 and 2 Cambridge University Press 1917 Pp 1-110 Price 8s —On the Summation of Propagated Disturbances in the Claw of Astacus, and on the Double Neuro Muscular System of the Adductor, by Keith Lucas A melancholy interest attaches to this communication for it is the last contribution to physiology made by that assiduous observer, Dr Keith Lucas, who at the early age of 37 died on Oct 5th, 1916 as the result of an aeroplane accident There seem to be two separate neuro-muscular systems belonging to the adductor muscle—one for the slow movements of the claw and one concerned only with rapid closing If the nerve to the adductor muscle is excited with a single stimulus the muscle may give either a small, slow contraction or a quick twitch according to the strength of the stimulus used The excitable substance whose stimulation leads to the twitch has the shorter excitation time and needs Richet the stronger current if the current duration is long described the summation phenomena in the claw of astacus, which belong to the type of "summation of propagated disturbances" in which the first stimulus though apparently The ineffective does send an impulse down the nerve impulse fails to cause a contraction of the muscle but ensures the success of a second impulse following it at a suitable interval of time —The Excretion of Urea and Sugar by the Kidney by Arthur R Cushny The commonly accepted view is that urea is a specific constituent of the urine and that a specific secretory activity is required for its excretion which does not seem to be required in the same way by the inorganic salts The physical properties of urea do not appear to justify its being treated as apart from the other constituents of the urine The concentrations of sulphates in the blood and urine bear an almost equal ratio with those of the urea, and the same is true of the inorganic phosphates and creatinin Even sugar, when it escapes by the kidney may undergo a concentration of from 0 2 per cent in the blood up to 10 per cent or more in the urine, and thus nearly rivals urea in extent of change The only sense in which urea can be accorded a special position in the urine is that it is normally present in large amount Heidenhain drew an analogy between the excretion of sodium sulphindigotate and that of urea His views, however, in regard to the passage of dyes through the kidney epithelium can hardly be maintained against the fact that dyes appear in the urine long before they occur in the interior of the cells, and that the maximum of staining of the epithelium takes place after the greatest concentration of the urine has passed off Still, the view is widely held that the concentration of the urea takes place in the tube cells quite independently of the activity of the glomerular capsule The author repeated Heidenhain's experiments, substituting chemical estimation of the urea in the kidney, finding that 1 When the spinal cord is severed no accumulation of urea occurs in the kidney, and, similarly phloridzin ceases to cause accumulation of sugar 2 Urea and sugar thus are not excreted in the way Heidenhain describes for the sulphindigotate of sodium, and all conclusions drawn from this analogy are erroneous The site of secretion for urea and sugar therefore remains undetermined, and experiments on mammals offer no grounds for supposing that it differs from that of the other constituents of urine —On the Localisation of the Calcium and Potassium Salts concerned in the Mediation of the Action of the Vagus Nerve on the Heart of the Frog, by W Burridge 1 Faradisation of the base of the frog's ventricle gives effects predominantly inhibitory when the heart contains blood and effects predominantly excitatory when the heart contains Ringer s solution 2 After treatment of the perfused frog's heart with potassium salts the capacity to be inhibited from the vago sympathetic trunk is lost and the capacity to be inhibited by the faradisation of the local nervous mechanism is regained 3 The capacity to be inhibited from the vago-sympathetic trunk following treatment with potassium is restored by calcium 4 It is suggested that calcium salts mediating the action of the vagus nerve on the frog's heart form an integral part of the structure, whatever it may be, on which nicotine acts 5 The potassium salts concerned in vagus action are situated at the "nerve endings" in the muscle —Some Observations on the Action of Guanidine on Frog's Muscle, by John S Meighan Other observers have studied the effects of this base and its neutral salts The spontaneous twitches it evokes in frog s muscles are less with higher than lower concentration of guanidine solutions Its ' curare," or paralysing, effect on nerve-endings in muscle seems to be due not to its action on muscle fibres, but either on the nerve endings or on the ' receptive substance" supposed by Langley to exist in proximity to the endings A moderate rise of temperature (5° C) increases its effect, but a great rise (25° C) does not completely destroy it The effect of cooling seems doubtful.—The Volume of the Dead Space in Breathing and the Mixing of Gases in the Lungs of Man by A Krogh and J Hindhard After a historical account of the measurements of the bronchial tree of a corpse (=140 c c) by Zuntz and Loewy in 1904 and the sampling of alveolar air by Haldane and Priestley s method (1905), and by other observers, the authors state that there is a clear and debatable issue between Haldane—who maintains that the dead space is a physiological and not an anatomical conception—and their own views They hold that the air in the air sacs (as well as in the atria) is not at the end of inspiration of the same composition throughout because the air inspired is incompletely mixed with the air previously contained The mixing takes place chiefly by diffusion and requires a certain time We must refer the reader to the original text for the methods used The following are the authors' conclusions 1 Just after inspiration the gas mixture in the lungs beyond the dead space (the alveoli taken in the widest sense of the term) is not uniform throughout The differences are usually slight but with deep and slow breathing they become considerable With deep and rapid breathing, as in muscular work the mixing seems to be again improved. 2 In attempts to determine the dead space of the air passages these facts must be taken into account if reliable results are to be obtained The very large dead spaces determined by Haldane and by Henderson and his collaborators are unreal 3 The dead space of a human subject is constant at pulmonary inflations below the resting position of the chest At larger inflations it increases gradually With a maximum inflation of the lungs the increase may amount to 100 c c 4 No evidence has been obtained of any unequal ventilation of different lobes of the lungs 5 The composition of the alveolar air should in most circumstances be determined preferably by calculation from the expired air, the volume of the expiration, and the dead space, When the breathing is deep the resulting increase in dead space should be taken into account, but during muscular work very slight errors only will usually result from not doing so, because the increase is small compared with the depth of respiration The direct sampling according to Haldane and Priestley, has in certain cases given rise to fallacious results 6 Our method of examining the composition of the alveolar air by a series of consecutive samples from the same breath is open to objections The errors are probably not large 7 The errors caused by incomplete mixing of the pulmonary gases in our circulation rate determination are much too small to be perceptible in experiments on normal lungs —The Mechanism of Cardiac Acceleration by Warmth and by Adrenalin, by C Lovatt Evans Much work has already been done in this direction by using the heart-lung preparation of a mammal as devised by Starling The factors which tend to diminish or increase metabolism and the efficiency of the heart are considered, analysed, and tested experimentally It was found that 1 The oxygen usage per beat although approximately constant over small ranges of temperature in the neighbourhood of the normal body temperature is increased at either extreme of temperature 2 The cause of increased metabolism at abnormally low temperatures appears to be dilatation of the heart with increase of the active surface, other factors are operative in both increasing and in diminishing this effect, the resultant only being apparent Similar considerations apply to the raised metabolism at high temperatures 3 The effects of adrenalin cannot be traced to such purely mechanical factors, the increased metabolism is apparently due to a direct and specific effect in increasing and accelerating the chemical changes associated with contraction —The Relations of Carbon Dioxide in the *Blood*, by George A. Buckmaster Very conflicting views are held concerning the state in which carbon dioxide exists in blood The statement of Pflüger in 1864 that a constituent of blood is capable of liberating carbon dioxide from the carbonates of that liquid is mentioned in most text-books on physiology The author was led to doubt whether a carbonate could possibly be decomposed by hæmoglobin or any protein or amino-acid of the blood If this view is found to be experimentally correct, then the total liberation of CO_2 from blood cannot be due to a protein It was found that neither hæmoglobin nor, indeed, any other constituent of the defibrinated blood is capable of freeing CO_2 from sodium carbonate and the same is equally true for solutions of the bicarbonate The author attributes any CO_2 which is evolved as being dependent on the development of acidity in the blood

Maternity and Child Welfare Vol I, No 3 London John Bale, Sons, and Danielsson Limited, 83–91, Great Titchfield street, W 1 Price 6*d* net —The third number of this useful periodical contains interesting articles by Lady Barrett, M D on the Midwife and her Share in the Protection of Motherhood by Dr Amand Routh on the Ordinary Diseases of Women which may Affect Pregnancy, and by Mr N Bishop Harman on Ophthalmia Neonatorum Shorter articles on Infant Welfare Centres, Food Values and the Training of Health Visitors are also included while the Annotations and Abstracts and Notes give summaries of some of the problems facing the medical and social worker among mothers and children and the attempts that are being made to solve them The idea of publishing sectional map of the British Isles showing the distribution of infant welfare centres, and the extent to which the work of each is developed and the amount of municipal help obtained, is a real inspiration This magazine is "edited in the interests of the mother and young child by a member of the medical profession, with the help of an advisory committee representing the various groups of workers," and is an excellent example of a form of literature for which there is much need The articles are written by experts from a scientific point of view, but in such language as to be perfectly intelligible to the voluntary worker (usually a layman) as well as to the nurse or health visitor

The Child Vol VII, No 6 March, 1917 —This number contains an important paper by Dr M F Boulenger on the management of the exceptional child in Belgium Before the war Dr Boulenger was medical director of the farm school for abnormal children at Waterloo (Belgium), and is now occupying a temporary post at the Darenth colony for defective children in Kent Abnormal children in Belgium were until 25–30 years ago accommodated in the lunatic asylums, while the first special institutions were prison like buildings, without classrooms or workshops, surrounded by treeless, macadamised airing courts In these wretched places children with faulty habits were tied all day on commode chairs, lying at night on mattresses reeking of ammonia. All this was changed by the pioneer work of two physicians who had studied pedagogy previously to their medical graduation, Professor Jean Demoor and Professor Auguste Ley, who, between 1900 and 1906, were the means of founding centres for special education in Brussels and Antwerp, and later in Ghent, with after care associations which arranged for the apprenticing of the boys and girls on leaving school The Société protectrice de l'Enfance anormale, with the late Minister of Justice, M Jules Lejeune, as its president, was successful in obtaining by its active propaganda, special tribunals for juvenile delinquents Dr Boulenger himself put forward the idea of the farm school in 1901 and pavilions were being erected on a large site in the province of Brabant when war broke out Temporary courses for teachers had, however, already been given in the province in 1914 Dr Boulenger generously acknowledges the influence of French and English ideas on his Belgian work he was himself a frequent visitor at the special schools in this country and looks forward in confidence, with the resumption of Belgian national life after the war, to further rapid development in his own country of the care and training of abnormal children

Reports and Analytical Records

FROM

THE LANCET LABORATORY

THE WHITE WINES OF ANJOU AND TOURAINE (FRANCE)

(ALEXANDER WOOD CAMPBELL, AND CO, 62, CRUTCHED FRIARS, LONDON, E C)

FOR medicinal or special dietetic purposes in which a light agreeable stimulant seemed desirable a preference has long been given to the German white wines of the hock and Moselle type (still and sparkling) They were chosen for their low alcoholic strength, their freedom from colouring matter, their small sugar content, and their low degree of acidity But according to a recent examination we have made of some specimens, it is quite evident that certain of the French white wines answer these requirements equally well The white wines, in fact, of Touraine and Anjou are in some respects better They are light, elegant and practically non acid We have received some 20 examples of these wines, a few of which we have submitted to analysis as giving a fair idea of their general composition and quality

(1) *Touraine Supérieur* (still) —Alcohol by volume 11·61 per cent extractive matters 2·55 per cent mineral matter 0·25 per cent sugar 0·27 per cent volatile acidity reckoned as acetic acid 0·12 per cent. fixed acidity reckoned as tartaric acid 0·82 per cent

(2) *Anjou Supérieur* (still) —Alcohol by volume 9·86 per cent extractive matters 1·55 per cent mineral matter 0·20 per cent sugar 0·26 per cent volatile acidity reckoned as acetic acid 0·09 per cent fixed acidity reckoned as tartaric acid, 0·86 per cent

(3) *Vouvray tête* (still) —Alcohol by volume 12 05 per cent extractive matters 2 40 per cent. mineral matter 0 20 per cent sugar 0 45 per cent volatile acidity reckoned as acetic acid 0 15 per cent fixed acidity reckoned as tartaric acid 0 71 per cent.

(4) *Touraine Supérieur* (sparkling) —Alcohol by volume 8 18 per cent. extractive matters 5 35 per cent mineral matter 0 15 per cent ; sugar 3 33 per cent volatile acidity reckoned as acetic acid 0·06 per cent , fixed acidity reckoned as tartaric acid, 0·67 per cent

(5) *Anjou Supérieur* (sparkling) :—Alcohol by volume, 12·05 per cent , extractive matters, 5 54 per cent mineral matter 0 14 per cent sugar 4 16 per cent volatile acidity reckoned as acetic acid, 0 07 per cent fixed acidity reckoned as tartaric acid 0·65 par cent

(6) *Vouvray tête* (sparkling) :—Alcohol by volume 13 43 per cent extractive matters 4 49 per cent mineral matter 0 19 per cent sugar 2 50 per cent volatile acidity reckoned as acetic acid 0 12 per cent fixed acidity reckoned as tartaric acid 0 51 per cent

These results bear out fully the claims that these French wines are, in regard to special dietetic requirements, not at all inferior to the German produce, and in certain respects they are superior This, at all events is the case in regard to a minimal amount of sugar, alcohol, and especially of volatile acid in the still wines, while the higher proportion of sugar in the sparkling wines is due to "liqueuring" These points may well deserve attention now that the supply of German white wines is cut off

ANTIPHLOGISTINE

(THE DENVER CHEMICAL MANUFACTURING CO , NEW YORK. LONDON AGENCY ST ANN'S ROAD, BOW, LONDON, E)

Antiphlogistine has been well described as a scientific mud which is externally applied hot and thick as a cataplasm for the relief of inflammatory and congested conditions In connexion with its application for this purpose we have already referred to this preparation, which is composed of a finely refined earth compounded with glycerine, iodine compounds boric and salicylic acids and certain antiseptic essential oils We are now informed that a poultice of hot antiphlogistine applied to the nose relieves the "stuffed up" feeling so often characteristic of the common cold In rhinitis and coryza favourable results are recorded. Applied over the nose in the case of a common cold at bed time, the patient is said to secure relief of the distressing symptoms, a restful night, and a general feeling of well being in the morning The combined application in this way of heat along with antiseptic oils and the like, may well produce an alleviation of such troubles

New Inventions

AN AUTOMATIC INTERMITTENT WOUND IRRIGATOR

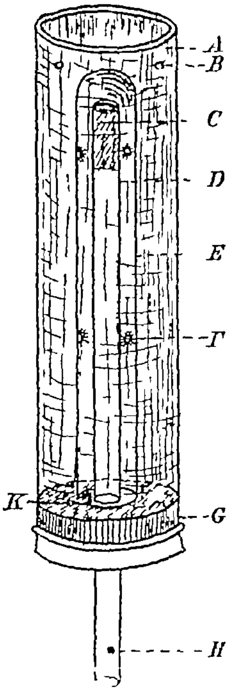
THE apparatus was originally intended for the intermittent irrigation of deep and infected wounds, and more especially of such wounds as are associated with compound fractures In dealing with these wounds a mode of treatment associated with the name of Carrel has received general use and recognition This treatment essentially consists in introducing into the crevices of the wound a number of rubber tubes each of about ⅛ inch diameter, gauze packing is lightly introduced into the wound around the tubes At regular intervals the tubes are irrigated through with a solution of eusol

Hitherto the irrigation was secured by regular manual irrigation with a syringe This method involved a considerable waste of time, much disturbance of the patient, and frequently the inducing of pain and irritation This apparatus was produced with a view to overcoming these disadvantages, and its origin is largely owed to Corporal Studd R A M C The apparatus embodies two simple mechanical principles (1) The property possessed by two adjacent and connected fluids of finding a common level , (2) the principle of the simple syphon

The original model (A) was composed of an outer glass tube and an inner bent tube As the outer jacket filled with fluid, the fluid rose to a corresponding level in the open limb of the inner bent tube, and when the bend was reached the syphon action was commenced and the outer tube emptied of fluid A simple air valve in the efferent limb of the bent inner tube obviates the occurrence of an air block

The times at which the irrigation will occur can be regulated by varying the rate at which the drip feed of eusol from the reservoir flows into the outer tube The interval will be the time which the fluid takes to reach the level of the bend The efferent tube is connected up by Y branches with as many of the rubber tubes as are required for the irrigation of the wound

FIG 1



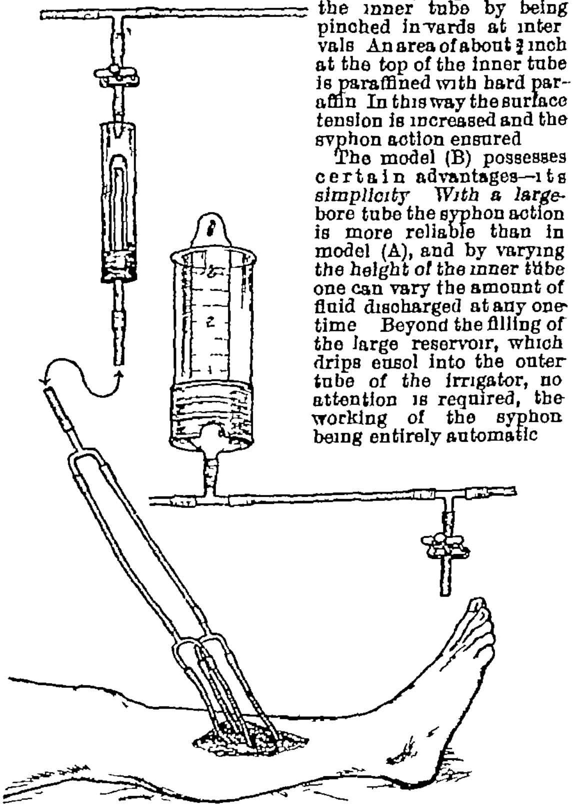
Syphon action irrigator Lieutenant Dunn s modification *A* outer glass tube *B* holes for suspending vessel *C* paraffined top of tube *D* inner glass tube *E* inverted test-tube, *F* pinchings in test tube to keep inner tube in position *G* rubber cork *H* air valve *K* inlet in lower border of test-tube

Lieutenant Dunn, R A M C , No 3, Mobile Laboratory, has produced a modification of the original model, and has kindly given us permission to include the description of the modification The apparatus is shown in *Fig* 1

A syphon is made by inverting a test-tube over a straight inner tube, and inlet is furnished at the open inverted end of the test-tube The test-tube is kept in position over the inner tube by being pinched in-vards at intervals An area of about ¾ inch at the top of the inner tube is paraffined with hard paraffin In this way the surface tension is increased and the syphon action ensured

The model (B) possesses certain advantages—its *simplicity* *With a large-bore tube the syphon action* is more reliable than in model (A), and by varying *the height of the inner tube* one can vary the amount of fluid discharged at any one time Beyond the filling of the large reservoir, which drips eusol into the outer tube *of the irrigator*, no attention is required, the working of the syphon being entirely automatic

FIG 2



Showing the method of distribution of the fluid from a central reservoir which may supply a *number of irrigators.*

It should be added that the tubes leading from the syphon should be made as perpendicular as possible, and that the cross section of the *distal* tubes should not be more than that of the proximal ones

An apparatus employed has been found easily adaptable to beds for the suspension and direction of the irrigator The height angle, or position of the *irrigator* can be variously altered

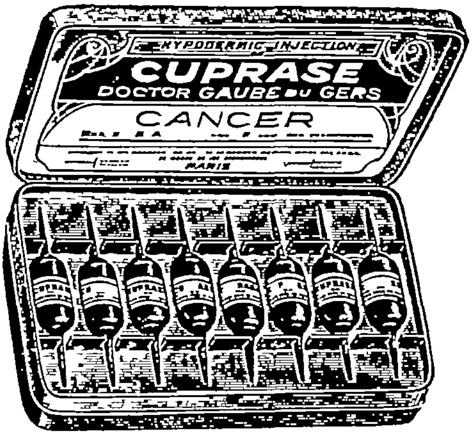
CUPRASE

For the Medical Treatment of CANCER.

xtract from Proceedings of the Royal ociety of Medicine February 1913 — Dr George Herschell, comparing lectric and chemical colloid copper ated .. Chemical colloid appears o give the best results In the following ases chemically prepared colloid was sed Experimentally it has been roved (1) That particles of colloid opper can be demonstrated in the ranulations of cancerous growths after wo or three injections of the colloid nd clinically (2) There is invariably reat relief from pain (3) Appetite and rength return and the patient puts on esh (4) There is in many cases a iminution in the size of the tumour) The injections are absolutely non-oxic although in many cases an in ammatory reaction is manifested in he cancerous growths

'As regards my own personal experi nce in the use of this method of treat ent in addition to my own cases I ave had an opportunity of observing he effects in the practice of some of my edical friends and in nearly all cases he progress of the disease appeared to e arrested.



CUPRASE is a Colloidal Copper hydroxide which is obtained chemically by the reduction of Salts of Copper in the presence of Albumosic Acid

This treatment has passed far beyond the experimental stage The numerous clinical reports from Doctors of repute in various countries give cases of a great variety In all of these **pain has been eliminated**, and in a good percentage **cures are claimed**, and in no instance **any undesirable effects**

IODARGOL

Special Colloidal Iodine.

NON-TOXIC PAINLESS	FOR THE TREATMENT of Gonorrhœa Acute and Chronic Urethritis Of Old Standing	DIFFUSIBLE ANTISEPTIC ANALGESIC

Cystitis and the Serious Complications of Gonorrhœa

In Ampoules and Phials for Injection or Soluble Bougies

IODEOL

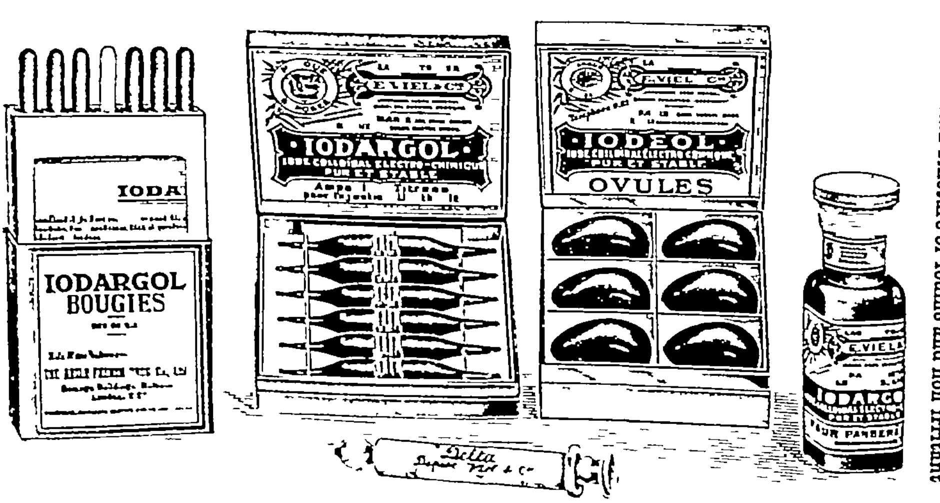
Electro-Chemical Colloidal Iodine

IODEOL CAPSULES (Internal Administration)

Perfectly tolerated Never cause Iodism Give off free Iodine Each capsule contains 4 grains of Colloidal Iodine

FOR GYNÆCOLOGY (Iodargol Ovules)

The Ovules slowly discharge the Iodine which penetrates deeply into the vagina mucous membrane giving rapid relief from congestion and pain Destructive to micro-organisms



IODEOL (Hypodermic and Intramuscular Injections)

Gives highly satisfactory results in the various forms of Tuberculosis The general improvement in the patient s condition is of a permanent character IODEOL for External application, Ten times more active than Tincture of Iodine and non irritant

PERSODINE

(LUMIERE)

Active, Tonic and Digestive Stimulant.

Composition

PERSODINE is in tablet form and consists principally of pure alkaline persulphates specially prepared in the Laboratories of the Brevets Lumiere Company These persulphates of Sodium Ammonia form a stable compound which has energetic oxidising properties being quickly decomposed in the presence of organic substances, and liberating sulphuric acid, oxygen and a neutral sulphate

Properties

Lumiere PERSODINE has made it possible to utilise the highly powerful oxidising properties of the alkaline persulphates which it had not been practicable to do until then

It is a eupeptic preparation which has a distinctly beneficial action on the nutrition It increases the appetite promotes dige tion and assimilation and consequently brings about an increase in weight.

Professor NICHOLAS reports very satisfactory results by the use of PERSODINE in cases of Anorexia, the early stages of Tuberculosis and *convalescents recovering from acute illness*

Dr GAREL published his experiences with PERSODINE in Hospital work from which the following is an extract —

' Our first experiments were solely carried out on patients in the *early stages of tuberculosis who suffered from loss of appetite* Little by little, encouraged by the splendid results obtained with these patients we decided to prescribe this remedy for very advanced cases of tuberculosis persons for whom there was no hope of recovery The most reliable results with PERSODINE will be obtained with patients in the early stages of tuberculosis even in the second period We have however, seen some fairly advanced cases greatly benefited by this remedy In short in most cases the action exerted is identical the appetite is excited the digestion becomes easier The general condition improves in every way *this is the almost uniform result of* the application of this remedy

Dr G MILLIAN, in a lengthy work on PERSODINE concludes as follows —

' PERSODINE may also find a place in the materia medica Its tonic and eupeptic action are its chief property it therefore produces an improvement in the nutrition and an increase in weight

" Consequently PERSODINE is specially to be recommended in the case of patients in the early stages of tuberculosis and of persons recovering from some acute illness who do not satisfactorily regain the use of their digestive functions of surgical patients after an operation of those suffering from chlorosis neurasthenia hyperacidity combined with gastric debility "

Doctor BETUEL *of Paris* has also published in the *Presse Médicale* the observations made by him both in his private practice and under the guidance of the senior doctors BERGER and BARTH during their attendance at the Beaujon and Necker hospitals

He states: ' Our observations were carried out on patients suffering from tuberculosis chlorosis and neuroses on convalescents recovering from acute illnesses to whom we added two cases of fractured thigh and finally on cases of overstrain

Clinical observations enable us to state definitely —

1 That PERSODINE possesses incontestable tonic digestive properties.
2 That it is well tolerated by the stomach and that it corrects any defects of the digestive functions
3 That its a tion on the nutrition *is mostly shown by a fairly rapid* increase in the weight of the patient

Professor ALBERT ROBIN has confirmed the tonic action of the persulphates and expresses himself as follows in a communication addressed by him to the Therapeutic Society " of Paris:—

I *am fully convinced that the improvement*, which it is possible to obtain in cases of tuberculosis is entirely brought about by a stimulation of the appetite This fact has led me to study on other patients the aperient properties of persulphates of soda they may be utilized in a large number of cases where a morbid state prevails *persulphate is from this point of view an excellent remedy in half the* cases *in which I have prescribed it as a tonic it has given good results* "

Doctor LEMOINE, Professor of Clinical Medicine at the Medical School of Lille:—*

PERSODINE is to be recommended in the apyretic torpid forms of tuberculosis during the two first stages and more especially during the first, when it gives astonishing results

Besides cases of tuberculosis PERSODINE is also to be recommended under the most varied circumstances—Chloro-anæmia, convalescents recovering from acute diseases surgical affections hysteria neurasthenia, overstrain

Therapeutic Indications

Anorexia, Tuberculosis, Chloro-Anæmia, Neurasthenia, Rickets, Dyspepsia, Convalescence, &c, &c, and—in a general way—in every case where suralimentation is advisable

HEMOPLASE

(LUMIERE)

Hemoglobin in its Natural State —Iron in most assimilable form

Composition

HEMOPLASE is a protoplasmic extract from the blood corpuscles of healthy animals absolutely free from tuberculosis HEMOPLASE is guaranteed to contain no globulary stromas antiseptics or other foreign substance

HEMOPLASE is, therefore a total extract of the corpuscle contents It embodies integrally the elements elaborated by the living cell, diastasic ferments hemoglobin in the natural state

Therapeutic Indications

Malaria, Anæmia, Hæmorrhage, Tuberculous Affections, &c

HEMOPLASE is prepared for Intramuscular or Hypodermic Injection this is in liquid form put up in ampoules Also in Pills for internal administration This HEMOPLASE in the dry state contains 70/ of natural hæmoglobin

In either form HEMOPLASE is absolutely harmless

HEMOPLASE in Cases of Tuberculosis

Dr GELIBERT in his communication to the International Tuberculosis Congress (Paris 1905) pointed out in the most convincing manner the action of HEMOPLASE in cases of tuberculosis

The conclusions contained in this important study based on an experience gained by 1250 injections administered to 118 patients are as follows: The plasmo-therapeutic treatment exerts on the cachexias in general and more especially in cases of tuberculosis an influence which is both remarkable and which has seemed to us more active than that of any other therapeutic method. "

HEMOPLASE in Cases of Cachexias

It would not be *correct to consider HEMOPLASE* as being a specific treatment in cases of tuberculosis.

The majority of the favourable results which it furnishes in such cases are entirely due to the stimulation to the intensive regeneration which it provokes in the entire organism In truth HEMOPLASE is principally the remedy for cachexias of whatever origin (cancer paludism anæmia hæmorrhages convalescence, &c.)

Mr J CHEVALIER* stated:—

' *In this preparation the hemoglobin is contained in such a state that it is easily absorbed by the red corpuscles and not eliminated by nature through the kidneys like the other preparations of iron which have been tried by this method* "

Doctors DUMAREST and BAYLE in attendance at the Sanatorium of Hauteville, have made prolonged experiments with HEMOPLASE in cases of tuberculosis Publishing the results of their observations in the *Marseilles Médical* they conclude thus —

1 HEMOPLASE never causes any toxic or inflammatory symptoms

2. The action of stimulation and of general dynamogenic solicitation exerted by HEMOPLASE is most manifest. It is an excellent nutritive stimulant and may prove an economic remedy The appetite the strength and the general condition are subjected in a general way to a rapid and energetic impulse "

HEMOPLASE in cases of Chlorosis and of Anæmic conditions

Doctor LOVITT *of Lille* in his inaugural dissertation before the Faculty of Medicine of Lille (July 1909) under the heading: Therapeutic and Experimental Researches concerning Plasmo-therapeutics in cases of Chlorosis stated that:—

HEMOPLASE yielded him excellent results and in certain cases he was able to realise the superiority of HEMOPLASE over other remedies containing iron

HEMOPLASE increases the total contents in hemoglobin and consequently the number of corpuscles Its action is not alone effective in the treatment of chlorosis but the improvements it brings about are lasting contrary to the results of other remedies

In an article Medical Future " Dr VIGNE thus sums up the physiological reasons, explaining the remarkable efficacy of the Lumiere HEMOPLASE for anæmic conditions —

Introduced into the circulation either by the subcutaneous or the digestive method it abundantly supplies it with hemo bin and the blood lipoids

.. As we have seen part essential pr the life
of the blood corpuscles will l ssimilated b s hemo-
globin absorbed by the fa or most

THE LANCET.

LONDON SATURDAY, APRIL 21, 1917

The Centralisation of Public Health

THE Food Controller continues to issue recommendations with regard to limitation of our food consumption, implying that further drastic limitation is advisable or even, under the circumstances, necessary Wheaten flour is his most serious concern at the moment, and every patriotic citizen is adjured to reduce his use of this staple article of diet in whatever form, by 1 lb per week But there is no certain conviction in the public mind that these and other recommendations are consistent with the physical health of the community No authoritative statement is issued, whether in fact they entail a reduction in mere eating which will be of advantage to the majority of us, or whether, under stress of necessity, we are to enter on a period of slight under nourishment, with corresponding but inevitable loss of working efficiency Medicine knows well enough that desire for food is not a fair guide to the individual as to his need for food intake, but the public should be told this and similar generalities by someone in authority These and other kindred matters need at the moment, *intensive* study by experts, who are in a position to make their pronouncements effective Doubtless there is expert medical opinion at the disposal of the Food Controller's Department, but it is questionable whether the powers of that bureau are sufficient to give effect to the wide sweeping recommendations necessary, in fact, here and immediately we come upon an urgent ground for the centralisation of public medical matters in a Ministry of Public Health

The six State Departments which have at present duties to discharge in connexion with the people's health are the Home Office, the Local Government Board, the Board of Trade, the Board of Agriculture, the Board of Education, and the National Insurance Commission, to say nothing of Somerset House, which has charge of vital statistics, and the Food Controller's Department Those familiar with the medical aspects of legislation in the making will remember how naturally it has come about that so many different State Departments are concerned Assuming that our readers know the particular medical work for which the various Departments stand guardian, they will realise that if any one of these Departments is to take over the mass of the duties of the other five it will be either the Local Government Board, having the sanitary administration of the country under its control, or the National Insurance Commission, having for its charge the care in sickness of 14,000 000 subscribers, whose needs are administered to by a large proportion of the available medical men on the professional roll If a new State Department be not especially created it will be necessary to reform or adapt one of these two for the conduct of enormously increased labours Each has strong claims, the Local Government Board as the bureau of preventive medicine under the existing system, and the National Insurance Commission, already actively engaged in medical treatment and in the furthering of scientific progress through its Medical Research Bureau There is between the two bodies but little overlapping or disputed territory of influence, so that a junction could take place without dislocation of public business, it could be of the loosest possible nature in the beginning and designed merely to obtain for the health of the nation one presiding force, and a centre around which later activities would be grouped

Failing the creation of a new department, which we should prefer but which at the moment can hardly be looked for, we think that the cause of medicine, and therefore the welfare of the country, would be best served by constituting the Local Government Board the central authority for the health of the people Its existing functions are closely connected alike with medicine and with the life of the people, so that any other health organisation acting independently from it would be in perpetual contact with it, and the delays and expenses following upon recurring discussions might largely counterbalance the advantages to be derived from the possession of a central authority The Unionist Social Reform Committee, whose recent valuable pronouncement upon the health of the people we reviewed last week, arrived at a similar conclusion, and we add to the reasons for their faith, which are so excellently adduced in their report, a further one, for it may have real weight The Local Government Board is heavily burdened with multifarious responsibilities towards the State, and there is sound reason for believing that once the central office for the health of the people, organised under its ægis, were grown vigorous under its far reaching influence separation would quietly occur, and a new Health Department would take in the public mind its proper position as one of the great Government bureaux A separation of the Department of Health from the Local Government Board, which took place in this way, would have the advantage that to the separating body there would be naturally adherent as a sequence of the past association, all those medical activities which cannot now by some movement of violent readjustment be torn from the Local Government Board and handed to the National Insurance Commission, or any other body, while the surrender to the new Department by the other Government Departments of the medical cares, thrust upon them through well meaning legislation, designed to meet various wants as they made themselves felt acutely, would naturally follow And of such a Department the National Insurance Commission, with the modifications in its working that are certain to occur in the course of time, would form one complete-side, linked by its Bureau of Medical Research to what is progressive in medical thought and to practical therapeutics by its responsibility for the medical treatment of a third of the population With a great Department so constituted we need have no fear for the future of the general practitioner or for the health of the nation No amount of centralisation or coördination can alter the fact that the individual sick person must be treated by the individual doctor, but the task will be carried out more efficiently as the care of the health of the people is better organised

Bone Grafting

WHILST bone grafting in the past has been rarely called for, and then chiefly to restore bones destroyed by osteomyelitis or new growths, the scope for its employment at the present day has been greatly widened by the injuries produced by gunshot wounds It is, therefore, a matter of pressing importance to examine the facts underlying this procedure in order to estimate its possibilities and the best technique for securing success, and Mr E W HEY GROVES, who has just received the Jacksonian prize for 1916, had good reason for taking this as his subject in the recent Arris and Gale Lectures delivered before the Royal College of Surgeons of England It was, we believe, OLLIER who first demonstrated by experimental evidence the capacity of living osseous tissue for regeneration and the viability of whole and fragmented living bones when used as grafts BARTH pointed out later that the rôle of even living bone grafts was largely passive, the graft itself possessing little osteogenetic power AXHAUSEN, however, succeeded in showing that on all the free surfaces of a living graft, as also in some of its Haversian spaces new bone was laid down, thus establishing the advantages of the living over the dead bone graft MACEWEN carried further the principle of the viability of the bone cell, showing that this principle dominated the whole question of bone growth, the periosteum being a limiting membrane and the underlying osteoblasts the osteogenetic factor It cannot, however, be said that the vexed question as to the functions of the periosteum has yet been finally settled MACEWEN'S experiments, which have been confirmed by numerous observers, mostly in America, prove that it has no independent osteogenetic rôle, but there is considerable body of evidence to show that the structure is nevertheless of great value in the transplantation of bone Probably under these conditions it acts as a vasoconductor and as a matrix for new bone cells

From a practical point of view, it is generally admitted that living autogenetic bone, with its periosteum if possible, should be used for grafting, but there are many points of detail which have been submitted to experimental study by HEY GROVES A graft may be fashioned as a peg and used as an intramedullary bolt This is a very unsatisfactory method If the graft is driven tight it remains indolent and inactive or breaks and allows the fractured bone to be displaced If it is loosely placed it will only establish vital relations when the bed in which it lies remains undisturbed by movement In other words two conditions essential for rapid vital success in bone grafting—viz, firm fixation and rapid vascularisation of, the graft—cannot both be secured in the intramedullary method, which is, moreover, mechanically weak On the other hand, living grafts rapidly establish vital union with a living bone bed, if they are fixed on to the cortex of the bone, so that they can be firmly attached and at the same time quickly acquire a blood supply from the soft tissues around In order to appreciate the conditions desirable for successful replacement of bone tissue it is essential to recognise that though living grafts may be viable, yet this viability is of a very limited character The osteoblasts on the surface of the graft do under favourable circumstances proliferate They contribute to that very narrow zone of new tissue which eventually joins the graft to its bed, and at a later period they may take part in the general increase in thickness which the graft undergoes But for the most part the bone graft, whatever may be its source, is a passive agent, differing from a metal plate chiefly in the fact that it finally becomes a part of the living tissues It has little or no capacity for rapid bone formation If, therefore, it is to replace a part of the skeleton which is lost it ought to be as large and strong as possible, and very firmly fixed in its place If living bone used as a graft could be made rapidly to produce new bone—i e, callus—then the matter would be quite different from what it is Then we should select a porous, vascular, cellular bone like a rib, divide it up into splinters or chips, laying these in the vascular bed where bone is lost, and keeping the part at rest for the same length of time as is required for the repair of a fracture, with the expectation of finding at the end of this time a regenerated bone formed by new callus But this is exactly what does not happen A graft simply laid loosely in soft tissues remains for a time and then slowly becomes absorbed A graft firmly connected with living bone grows to it, but not for many months does it show active osteogenesis The more a bone graft is divided up into chips the less certain is its survival or its growth Bone chips laid in a thin layer on a raw bone surface may quickly become the centre of callus formation, but the same chips filling a large bone gap simply remain indolent or become absorbed, because the majority of them have no direct contact with the only kind of tissue which can support them Even MACEWEN, who is responsible for the idea of the osteogenetic value of small bone fragments, admits that he could not make bone dust grow, though he attributes this to the injury of the bone cells by heating Unfortunately, however living bone dust is produced it is found to retain such feeble capacity for bone reproduction as to be quite worthless The ruling factors appear to be these the union of a living bone with its bed is at first by means of a cellular granulation tissue which ossifies comparatively slowly This union is always accompanied by a process of rarefaction of the adjacent bone tissue, which whilst it lasts is a source of weakness Therefore the first "taking" of the graft and its final incorporation with the skeleton will be greatly aided by the extent, the accuracy, and the firmness of contact between the old and the new tissues If the part concerned is the spine or the skull, where little or no movement of the bone is possible, then correspondingly little suture is required But if the graft is to fill a gap in a tibia, femur, or humerus, then mechanical fixation is a matter of the utmost importance There has quite rightly been a reaction against the routine plating of fractures, but because metal plates and screws are only desirable as temporary suture agents there is no reason to ascribe to them an inhibitory influence on bone growth

No doubt the most ideal bone grafting is that which, like the joiner's "dovetail" work, implies an exact fitting of one part into another so that no other fixation is necessary But this is seldom possible in the repair of long bones Fixation, then, should be by nails, screws, or wire, and, if the size of the bone will allow, by ivory pegs or bolts The alternative to this is the use of animal ligatures only, supplemented by extensive plaster of Paris splinting But this method is very insecure and uncertain in the case of the long bones, and the long immobilisation by plaster does everything to retard vascularisation and osteogenesis in the new tissues The experimental comparison of dead and living bone pegs, when these are used as nails driven into living bone, reveals the fact that they both behave in exactly the same way The organic union between the peg and its bed seems to be as speedy and as firm in one case as in the other There would appear, therefore, to be no object served by making bone nails for fixation purposes out of the patient's own tissues when ivory nails can be accurately prepared beforehand In clinical practice all these principles are of the utmost importance Grafts have to be carefully planned, fitted, and fixed if they are to give speedily successful results Apart from the possibility of homoplastic grafting, which presents many practical difficulties, the best bone to use is the patient's own tibia, from the mesial surface or crest of which a long and strong graft can be prepared It should considerably overlap the gap which it has to fill and be made to fit into slots in the ends of the bone to be repaired, and there fixed either by ivory bolts or nails or by wire

But in the repair of gunshot wounds of bones, unfortunately, there are other elements which very gravely complicate the problem These are latent sepsis, the injury of the soft parts, and the presence of large scars For months after a wound has healed, especially that of a septic comminuted fracture, the tissues harbour the organisms of sepsis, which may flame into activity if the wound is reopened To avoid this disaster a period of three to six months should be allowed to elapse before grafting, and by means of massage, active and passive congestion, the tissues may be either cleared of their infection or made to declare the presence of pyogenic agencies In important cases it is indeed, wise to do a preliminary operation for the clearing out of debris and the removal of scar tissue, and to postpone the implantation of bone for another considerable interval unless this preliminary operation heals quite smoothly Large superficial scars are a great source of danger They will almost inevitably slough away after any plastic operation Therefore either before or after any grafting operation such scars must be replaced by sound skin, and eventually the graft ought to be buried in muscle or fascia, so that it does not immediately underlie the skin wound In its practical aspects bone grafting as applied to the treatment of gunshot wounds is so new and important that all surgeons engaged in this work should be urged to publish all their cases, bad and good alike, in order that a sound opinion and practice may result from their experience

Professional Organisation among Medical Men

WE are accustomed to hear from medical men that their profession is an unorganised body, and, therefore, at the mercy of the politician, who can always obtain his way from the whole by playing off some section against the others We are equally familiar with the complaints made on political platforms, or even in the House of Commons, that the medical profession is such a perfectly organised ring that it can impose its will upon the legislature of the country Of course, each statement is inaccurate, and when we say that a practical consensus of medical opinion has great weight, but that circumstances seldom elicit such a consensus, we have put the position in fairly correct terms That this might well be so will, we think be the opinion of our readers, when they study the section upon medical organisation, which will be published immediately in a supplement of the *New Statesman* dealing with professional associations The authors of this section go very fully into a complicated story, and have succeeded in making it clear, though unfamiliarity with some of the details betrays them now and again into incorrect generalisations The Medical Act of 1858, for instance, has never been transformed to include the ideals of the earlier medical reformers, for so far from creating one portal of entry to the profession, the number of portals have been steadily increased A well deserved compliment is paid to the energetic tactics of the British Medical Association, whose complicated machinery is carefully explained—so carefully that the analysis of the constitution will be useful, perhaps, to many of its members The most interesting section is the one dealing with the relations of the doctor to the community, wherein the reasons dictating the professional attitude are well analysed and, we think, fairly handled, though in one or two places the particular difficulties of the medical man towards a public, which cannot be expected fully to appreciate the basis of his conduct or practice, are not brought out We strongly recommend the whole article to our readers as forming a useful synopsis of their professional position, made from outside their ranks

Annotations.

"Ne quid nimis"

THE PREVALENCE OF MEASLES

MEASLES has interfered much with the amenities of civil and political life during the last few weeks, and-there is a widespread impression that it has been more prevalent and more severe than in previous years Within the compass of a single week 87 deaths from this disease have been recorded in London, 18 in Manchester, and 19 in Birmingham, while epidemics have been reported from most other large towns School authorities have in many places been obliged to take action infant schools in Dublin were closed early in March and several of the public schools in this country were obliged to take the same course Measles presents indeed to the school medical officer a problem of much complexity which is likely to claim attention for some time As was shown by Dr J H Thursfield in the Local Government Reports for 1912–13, the serious pulmonary complications of measles are due to a mixed infection or one superadded to the primary infection It is obvious that where large numbers of cases occur in an institution there is an increased opportunity for the individual case to find a secondary infection to which he is susceptible Under these conditions a comparatively rare complication such as mastoid infection may become frequent in an institution where measles is prevalent and one such secondary infection present To the school authorities it would be a great convenience if pupils arrived immunised against the disease in the only way at present known, that of having already had an attack As 90 per cent of the mortality from measles occurs in children under 5 years it is highly advisable to protect them from infection up to this age, although in the mortality from measles at any age it should be remembered that sanitary conditions play the leading rôle In the year 1914 while the death rate from measles per 1000 living for London as a whole was 0 31, that for Shoreditch was 1 02 and for Hampstead 0 02, or one fiftieth of the mortality in the more crowded area It has been estimated that in general the mortality from measles of children among the well to do classes is only one fourth what it is in poor households But whether children from the age of 5 to 10 years should be protected from sources of infection with the same care is a matter on which opinions may well differ Unlike scarlatina, measles appears to be equally infectious at any period of life up to an advanced age The chances of escaping exposure throughout life are remote, and the period of election might therefore, for many reasons, be the pre school years So acute has been the course of the disease amongst an entirely susceptible population, as in the classical examples of the Faröe and Fiji outbreaks, that some authors have assumed a degree of hereditary immunity among the general population handed on from parent to child In harmony with this view is the admitted infrequency of measles in infants up to the age of 3 months, and a recent observation by Dr Charles Herrman, of New York, that infants at a slightly greater age (3–5 months) contract the disease in such a mild form as to produce no effect on their weekly weight chart These characteristics of the epidemiology of measles demand further study, which should lead to an advance in our knowledge of the best methods of avoiding any considerable mortality Prevention of the disease itself can, however, hardly be hoped for until the nature of the measles infection has been discovered

BREAD ECONOMY

AN exhortation to economy in bread is at the moment the Food Controller's message to the nation in regard to the food supply We are asked to reduce our bread ration and to forgo the use of wheat stuffs at afternoon tea It may naturally be asked how bread, which is commonly called the staff of life, can be replaced in the bodily economy In considering this question we should remember the rôle of bread in the dietary, which is to supply the carbohydrate necessity in the daily intake "Take care of the calories and the protein will take care of itself" is Professor Bayliss's adage, and it is clearly waste of time to discuss the value of bread apart from its carbohydrate content when substitutes of equal calorific value are available Oatmeal, barley meal and flour, maize meal and rice can be freely used without any apparent physiological disadvantage to replace or to eke out our supply of wheat flour The view that wheat is an essential article of diet must therefore be regarded as ill founded, a mere dietetic fetish Other more available starchy foods should promptly come into general use, and the immediate desideratum is an earnest and practical study of the best and most palatable forms in which to present these substitutes on the table If that were done by our cooks, bakers, and heads of families the idea of a physiological disaster might be put aside The extreme importance of this simple temporary step should be universally realised, since its adoption may well mean the successful avoidance of great hardship, especially to the poorer parts of the community The appeal to cut down the consumption of wheat flour should find a ready response from every patriotic individual in the land

VOLUNTARY ACCELERATION OF THE HEART-RATE

IT appears that there are a few individuals who possess the extraordinary capacity of voluntarily quickening the heart rate, 13 instances in all have been recorded, and another is reported in some detail by Dr John Favill (Chicago) and Dr Paul Dudley White (Boston) in the current issue of *Heart* (vol vi, No 3 p 175) The quickening commences almost immediately after the subject has willed it and one second after the word is given by the observer The history of how such voluntary acceleration came to be acquired is interesting There had never been any organic disease of the heart At the age of 15 a quickened pulse rate was noticed after mental excitement or physical exertion Cross country running about the age of 20 caused no cardiac symptoms even when seven miles were covered in 40 minutes At the age of 22 the effort of climbing a small mountain sent the pulse rate up to 190 Two years later the sensations which have since been found to accompany voluntary acceleration were induced for no known reasons and repeated occasionally in the following years Two years after, in 1913, the power of voluntary acceleration was discovered by chance It has been possible to exert this power ever since Such quickening is dependent on a distinct effort of will, and the strain is as tiring as that produced by holding up a heavy weight, it is not a succession of efforts but one that is continuous Relief is felt with the cessation of the acceleration During the quickening there is a feeling of fullness or tingling over the whole body A mild exhilaration occurs for a few seconds, and moderate fatigue follows if the paroxysm is induced several times The phenomena associated with the acceleration are as follows The maximum increase in rate observed has been one of 96 beats, the rate changing from 104 to 200 An electrocardiographic record shows a quickening, on another occasion, of from 98 to 161 The least increase has been 30 beats The maximum speed is reached after several beats have occurred, the high speed is maintained for a few seconds, then gradually descends to a normal rate In the paroxysm the blood pressure is slightly raised, the pupils dilate, and some sweating occurs on the palms of the hands The acceleration is suggested to be due in great part at least, to the action of the accelerator mechanism and not chiefly to the withdrawal of vagal action, since acceleration can be induced even after atropine has been given, and since the character of the electro cardiographic curves during the quickening is similar to those which occur when the sympathetic nerves are experimentally stimulated It is reported that this curious faculty has on two occasions been of service to its possessor "Once in a condition of great fatigue in a hot operating room, and again while watching cattle killed in a great packing plant for the first time, sensations of impending syncope were felt On each occasion voluntary acceleration, with its rise of blood pressure, was induced and the feeling of faintness vanished at once" These observations are of interest as a contribution to the study of variations in the cardiac rhythm, and their publication may lead to the discovery of similar cases The term "voluntary acceleration" remains in some sense a misnomer, unless conclusive evidence is present of a direct influence of the will upon the cardio accelerator mechanism In the case recorded the feeling of strain described suggests that some powerful voluntary contraction of muscles was involved to which the acceleration might have been a secondary or associated phenomenon

SOME ESSENTIAL DIFFERENCES BETWEEN ANIMAL AND VEGETABLE FATS

THE existence of accessory factors in various foods may be regarded as a well established fact, and it is now becoming recognised that there is a considerable variety among these accessory foods Experiment shows that young rats will not grow if fed on polished rice and butter, or on rice and wheat germ, while if both wheat germ and butter are added the diet becomes adequate Milk contains both of these factors There seem to be two groups of these substances one is the 'fat soluble A' factor and the other contained in wheat germ is soluble in water, not in fat, and has been called the "water soluble factor B' In a recent volume of the *American Journal of Physiology* (vol xli, 1916) E V McCollum directs attention to the distribution in plants of the "fat soluble A, the dietary essential of butter fat The question arises in view of the present consumption of margarine and other butter similars, whether any of the substitutes can actually replace butter in the diet The question has been investigated in America by several observers and in this country by Halliburton and Drummond to ascertain whether the chief butter substitutes now upon the market contain the important fat-soluble A factor Young growing rats were used, their dietary consisting of purified food stuffs, such as caseinogen, starch, dextrin, sugar, the water soluble B factor, together with the addition of the fat to be examined A rat fed on such a diet with the addition of lard was eventually found to decline and die, but if the fat soluble accessory substance A was added in sufficient amount and not too late, the life of the animal was saved and normal growth ensued. Some of the results may be summarised thus —

' Oleo-oil" margarines —In these the basal fat of low melting point oleo-oil" is prepared commercially from beef fat Osborne and Mendel in America showed that this commercial product contains the accessory factor associated with fats, and this form of margarine was found to be equal to butter fat in the nutrition of young rats For vegetable oil margarines the basis is a cheap vegetable oil, e g, coconut and peanut oil Few, if any, of the chief vegetable oils—corn, olive, sunflower seeds soy bean, wheat, linseed, arachis, coconut and cotton seed oils—contain the fat-soluble A Rats do not grow to adult size when any one of these oils is the only fat present in the dietary Margarines made from these oils are deficient in the important fat soluble factor

Vegetarian suet and lard substitutes.—*Those examined* were free from the fat soluble factor, one was a deodorised coconut oil and the other a hydrogenated cotton seed oil preparation corresponding to ' Crisco," sold extensively in the U S A as a lard substitute, but is a useless substitute for butter

The points raised are obviously of great practical importance and their solution essential to the proper understanding of some of the food problems which the war has forced upon our notice

A CASE OF POST-OPERATIVE TETANY

Dr H W Stenvers records[1] a case of tetany occurring after the operative removal of the thyroid gland, or tetania parathyreopriva, as it is sometimes called, in which relief of the symptoms was obtained both by the administration of parathyroid gland tissue by the mouth and by the transplantation of parathyroid glands The patient, a girl aged 20, had shown signs and symptoms of exophthalmic goitre four years previously, and had had the right half of the thyroid gland removed at that time Eighteen months later a second operation became necessary, and the other half of the gland was taken away While the patient was still on the operating table she had a violent and painful attack of tetany Ever since that time she had been subject to attacks of tetany, which were worst just before the menstrual periods latterly the tetany had been so severe as to prevent her from working When she came under the care of Dr Stenvers she was thrown into a state of forcible and painful tonic spasm, most marked on the right side, by any sudden mechanical, optical, or auditory stimulus The physical signs of Chvostek, Erb, and Trousseau, characteristic of tetany, were all well shown by the patient particularly on the right side Dr Stenvers draws attention to the rapidity with which tetany followed the removal of the last of the parathyroid glands in this patient As a rule many hours or days elapse before tetanic spasms occur in these cases, and a quotation from Marine is given to show that in dogs tetania parathyreopriva may develop in as little as seven hours Dr Stenvers concludes that after her first operation his patient was living in a borderland condition of latent tetany Discussing the treatment of this form of tetany, he notes that the daily exhibition of a few decigrammes of fresh parathyroid tissue from the horse gave his patient great relief This was shown in three ways firstly, the muscles became much less excitable to the interrupted galvanic current, secondly, the excretion of creatinine in the urine was lessened, thirdly, the general condition of the patient improved The importance of creatinine in tetany is this, that the tone of the voluntary muscles is much increased in conditions in which the excretion of creatinine is increased Before the parathyroid treatment Dr Stenvers's patient was excreting about 13 decigrammes of creatinine daily, but during the treatment this figure fell to about 6 decigrammes Dr Stenvers notes that horses' parathyroid glands are hard to come by during the war, his attempts to make use of the parathyroids of pigs failed, apparently because he was unable to find these organs in the animals The next step in the treatment consisted in the implantation of three parathyroid glands by Professor Laméris, taken from patients with exophthalmic goitre The results were excellent, four months later the patient was still able to work, though no longer quite free from the tetanic spasms, and the urinary creatinine had risen to nearly 9 decigrammes a day Three months later the girl was still at work and delighted with the result of the treatment, the tetany was present still, but painless

---

THE INVENTOR OF ESPERANTO

Lazarus Ludwig Zamenhof, whose death is announced at Warsaw on Saturday last, was 57 years of age and a native of Bialystok in Russian Poland Of delicate health, he was intellectually precocious, reading and writing well at the age of four In 1873 Zamenhof's father having been appointed inspector of private schools at Warsaw, the boy finished his education there, going on to Moscow University to study medicine After qualifying in 1885 he returned to Warsaw, where he specialised as an ophthalmic surgeon Warsaw, with its mixed population of Russians, Poles, Germans, and Jews, early directed Zamenhof's attention to the need for a common language as an instrument of better civic and racial understanding his idea being well expressed in the verse of the Esperantist hymn "La Espero" —

Sur neŭtrala lingva fundamento
Komprenante unu la alian,
La popoloj faros in konsento
Unu grandan rondon familian

Zamenhof drew attention to a preliminary form of Esperanto in 1878, but it was not till 1887 that he published his first text book Warsaw did not greet its local prophet with enthusiasm, and it was only after obstinate opposition that his propaganda spread through to Poland, Russia, Germany, Sweden, France, and finally in 1902, to England In 1905 the first Esperanto Congress was held at Boulogne sur Mer and since then large gatherings have collected annually at Cambridge, Dresden, Barcelona, Washington, Antwerp, and Cracow, at which all the nations of the world have been represented Medicine and pharmacy are now represented by the *Tutmonda Esperantista Kuracista Asocio* and the *Internacia Esperantista Farmacista Asocio* respectively, and a medical periodical, *La Kuracisto*, only ceased to appear on the outbreak of war Zamenhof therefore lived to see a large measure of recognition given to his ideal of the drawing together of the races by means of a language which could be commonly used in addition to their native tongues

HYDROCARBONS IN FISH LIVER OIL

The discovery of a high proportion of hydrocarbon in fish liver oil is remarkable, and should set chemists and physiologists thinking as to how its presence is to be explained in place of the usual saponifiable fat or glyceride Mr A Chaston Chapman reported at a recent meeting of the Society of Public Analysts that a sample of oil from certain species of sharks caught off the coast of Morocco had been found to contain as much as 90 per cent of unsaponifiable matter, consisting almost entirely of a new unsaturated hydrocarbon to which the name of spinacene has been given and the formula $C_{30}H_{50}$ assigned Apparently there are two main classes of shark liver oils, the one having a specific gravity of about 0 86 and containing a very high percentage—up to 90 per cent—of unsaponifiable matters, and the other having a specific gravity of 0 91 to 0 93 and consisting largely of glycerides with smaller proportions of unsaponifiable matters containing cholesterol As Mr Chapman points out, the fact that these two classes of oils have totally different chemical characters and could not therefore be used for the same purposes makes it desirable to qualify the simple designation "shark liver oil" by a statement of analysis In soapmaking, of course, an oil containing so much hydrocarbon would be practically useless Should such oil find its way into cod liver oil the therapeutic intentions of the prescriber may well be set at naught, hydrocarbons, as is well known, possessing no nutritive value

The next session of the General Medical Council will commence at 2 p m on Tuesday, May 22nd, when Sir Donald MacAlister, the President, will give an address

Sir Ernest Goodhart and Mr Gordon Goodhart have given the sum of £300 to Epsom College in memory of their father, Sir James Frederic Goodhart, who was one of the earliest pupils at the College

Royal College of Surgeons of England — A quarterly meeting of the Council was held on April 12th, Sir Watson Cheyne, the President, being in the chair In accordance with the recommendation of the Jacksonian Committee the Jacksonian prize for the year 1916 was awarded to the author of the dissertation bearing the motto "Experientia docet" when the envelope bearing this motto was opened, the President announced the name of Mr Ernest W Hey Groves The subject of the dissertation was "Methods and Results of Transplantation of Bone in the Repair of Defects caused by Injury or Disease" It was resolved that the subject for the Jacksonian prize for the year 1918 should be "The Injuries and Diseases of the Pancreas and their Surgical Treatment ' Sir Arthur Thomas Sloggett K.C B , C M G , was elected a Fellow of the College under the section of the charter relating to Members of 20 years' standing Mr Charters J Symonds was appointed a representative of the College on the Senate of the University of London for a period of four years in the vacancy occasioned by the expiration of the period of office of Sir Rickman J Godlee The President reported that, together with the President of the Royal College of Physicians of London, he had received a deputation from the National Medical Union on the subject of the mobilisation of the medical profession

TUBERCULOSIS IN AUSTRALIA

THE report on tuberculosis which has just been issued by the committee appointed to consider and report on the causes of death and invalidity in the Commonwealth of Australia[1] is to be welcomed as a distinct contribution to the knowledge of the subject. The personnel of the committtee, over which Mr James Matthews, an Australian Member of Parliament, presided, adds material weight to the character of their conclusions Sir H B Allen's pathological and general knowledge is supplemented by Dr J H L Cumpston's special information, for he had previously acted as a Royal Commissioner when principal medical officer of Western Australia, and then made a most valuable report on the incidence of miner's phthisis Dr A Jeffreys Wood, the fourth member of the committee, has particular experience of children, and thus rounds off the equipment of a well chosen body

Factors concerned in the Control of the Disease

The report displays many points of especial interest in the light of the peculiarly favourable climatic conditions for chest diseases existing over the greater part of the Commonwealth and the superior conditions of living among the general mass of people The problem divides itself, there, as here into two questions To quote the report —

> The whole study of tubercle must be of a twofold character—firstly in relation to exposure to infection with the bacillus, and secondly in relation to the resistance of the individual.

The second problem which time is showing to be the more important of the two, has hardly received the consideration its importance deserves. The report states —

> The two principal factors concerned in the determination of the results of infection are (1) Personal resistance of the individual infected and (2) effect of environment on the health of the person. With regard to the comparative importance of either of these two factors very little can be said in the present state of scientific knowledge yet it is becoming increasingly evident that they are the main factors concerned in the cure and control of the disease.

The principal attention of the report is directed to the infectious side, although the evidence brought together does not suggest that the following up of that side so exclusively has yielded results commensurate with the expenditure

In England and Wales, at any rate, the fall of the death rate has not been materially altered by the knowledge that the disease was infectious, which was established in 1884 with Koch's discoveries, although in Australia there has been a more definite improvement since that discovery This especially holds in Queensland, where the top year of a rising death rate was 1884 with 196 per 100,000, as against 183 in England and Wales, whereas Queensland s death rate in 1914 had fallen to 42 while England and Wales still stood at 101 more than double

In this connexion it is interesting to contrast the position of the question in the old country, with its death rate uniformly falling during the whole of the last century, with the various Australian States which reached their top on a rising death rate for pulmonary tuberculosis in the following years —

New South Wales ..	(1885) 116 ..	(1914) 64
Victoria ..	(1887) 153 ..	72
Queensland	(1884) 196	43
South Australia	(1888) 118	64
Tasmania	(1887) 115	45

In England the rate has uniformly fallen —

In 1870 ..	241	In 1884	183	In 1904	124
1874 ..	209	1894 ..	138	1914	101

Making a comparison between the rate before 1884, we find Koch s discovery year and subsequent years —

	1875	1885	1895	1914		1875	1885	1895	1914
England	220	177	139	101	Queensland	141	192	96	43
New South Wales	105	116	81	64	South Australia	100	99	95	64
Victoria	130	145	132	72	Tasmania	—	111	75	45

These figures suggest a somewhat generally held view among medical men in Australia that infection is possibly a matter of more importance in countries with higher average temperatures, which means that education concerning and precautions against infection are more valuable in countries belonging to the warmer latitudes

Notification —Death rate in Relation to Age —Distribution

As regards notification, the question does not seem to be in a much more satisfactory condition in Australia than in this country, as the notification proportions to death rate show that the average case is not notified till the later stage of the disease In this connexion a great improvement will occur when the death rate figures are published in definite periods, after notification has occurred, say, one month, six months, 12 months, 18 months, and so on, then a reasonable comparison of results can be instituted between the various States It will probably be found that by far the greater number of deaths occur within six months of notification, suggesting that the present practice is to notify long after the infectious state has been reached, which in itself would more than nullify the procedure

In relation to the age at which tubercle is most dangerous, a most interesting set of figures is given which demonstrates that the death rate from tubercle does not in males differ very much in accordance with age, rising slowly from 111 per 100,000 between 25 and 29 till it reaches its maximum in males between 55 and 59, or 185 per 100,000, then slowly falling to 137 between 70 and 74 In women the incidence is quite different The corresponding figures rapidly rise from 113 per 100,000 between the ages of 20 to 24, to a maximum of 135 per 100,000 between 25 and 29, and as rapidly fall to 121 between 30 and 34, gradually diminish to 91 per 100,000 between 60 and 69

The rate is never so high for women as men after the thirtieth year The high figures for women in early life are probably due to child bearing and the sexual periods which have such an injurious relation to tuberculous women, and in this connexion it must be remembered that the healthy woman marrying the tuberculous man finds far greater danger of infection than if the risk were the other way about

The distribution of tuberculosis in Australia is a matter that must attract considerable attention The figures are for the year 1911 and for men only (the total number of deaths analysed being a little over 2000), but they yield first of all the statement that tubercle is most fatal among those of independent means, being at the rate of 222 per 100 000, independence being apparently even more fatal than mining and quarrying with its 200 per 100,000, industrial 153, professional and commercial 120, winding up with pastoral and other primary industries at 25 per 100,000 This suggests some reflections, and accords with the view held by many that resistance to tubercle is less among the well-to-do classes, and manifestly it can in their cases be neither housing nor want, but the disease catching them at their best, with no reserve, and with little grit, so to speak, putting the balance on the side of the bacillus This return is very interesting from a treatment point of view, and suggests that the rich suffer from insufficient stamina and that an increase of hardening should be aimed at for their successful treatment The pastoral industry, on the other hand, probably working longer hours at a slower pace than any other, gives the best results

Preventive Measures

Years ago the prevalence of tubercle in the colony was supposed to be due to importation of cases attracted by the suitable climate, but statistics put an end to that fallacy, as it is found that 72 per cent of the deaths occur amongst those born in the colony and 13 5 with over 20 years residence, while only 6 2 occurred within five years of arriving In a democratic community like Australia it is interesting to see that the treating of tuberculosis as a penal offence is suggested That is all the more striking, as the view which regards infection as being the main cause of the death rate has had little fresh evidence brought forward in its favour Although gross infection undoubtedly does act injuriously, only in about 30 per cent of the cases is any contact proved, which is an insufficient number to justify the drastic powers suggested It must be remembered that Sir H Allen's experience in the post mortem room of the Melbourne Hospital confirmed the now generally admitted fact of the almost universal tuberculous infection in later life, as first practically demonstrated by Naegeli and von Pirquet If this is so, the line of success must lie in seeking to increase the resistance rather than in the diminution of infection It must be remembered that smaller incidence in women especially at the later period when men are most subject, almost proves this contention The men and women graph at the end of the report is a most eloquent statement The lowest women's death age is from 50 to 55, and the highest death age for a man is 55 to 59, women then being under 80 per 100,000 and men over 180 per 100,000 an impossible position if infection were the main cause of death rate

---

[1] F 11 A J Mullett Government Printer State of Victoria.

It should, we think, be remembered that penal clauses militate against their own success as tending to prevent the notification of earlier cases The State should in its own interest, be prepared to provide beds for all later cases desiring them There should be no such position as "hospital beds full, no room for more" Likewise every effort should be made to remove notably infectious cases, on ordinary sanitary grounds, from lodging houses and places of public resort. But interference with the home must be very carefully safeguarded except by the legitimate means of education and persuasion, save in those cases where poverty and dirt render some alteration necessary in the interests of the individuals themselves as well as the community

Far more important in our view is the question of proper sustenance for the dependents of the tuberculous, a point at present more responsible for the extension of the disease than any other cause by diminishing the resistance, from insufficient food, to those already probably considerably infected. Here comes in the question of the extreme value of the invalidity pension of the Commonwealth, which might well be copied in this country It appears fair that the community should see that those to whom it supplies pensions should take proper precautions and the pensions investigation suggested in the report has all in its favour By investigating the condition of the pensioners many important problems could be settled to the material welfare of the community How important these pensioners are to the Commonwealth finances is indicated by the payment made under the Act of £44,000 in the last five years We are glad to see that the report suggests that the pensions should not be interfered with on the patients entering hospital

Administrative measures, the report says, should be adapted to the knowledge and experience already available The latter are, as we have seen, by no means the same in Australia as in this country, but there, as here, the keynote of success probably lies in the dispensary system, which keeps in touch with the tuberculous in their own homes "Considerable extension," the report's recommendation runs, "of the dispensary system is required with the object especially of detecting the early cases before they reach the stage when they are infectious for others A necessary corollary to this is the provision of sufficient sanatorium and hospital accommodation to afford a bed for every early case" The object of this provision being contained in the statement, which we can cordially endorse "They go to the sanatoria for cure and for education, and cure rests mainly upon education"

Another useful suggestion in the report is to the effect that the school medical inspectors be supplied with a definite standard of nutrition in school children for them to work upon Undoubtedly the undersized and undeveloped are the most susceptible to tuberculous diseases in youth We think it probable, however, that a different standard would be required for each colony and possibly for different degrees of latitude in each colony The suggested observation of nutritional percentages[2] at regular periods by the teachers would probably bring early tubercle more under observation than any other single simple measure The effect of different latitudes on the development of a similar race in regard to tuberculosis would, in addition, yield material of enormous importance to the problem of the white development in Australia, a matter more nearly touching national life in the Commonwealth than in any other part of the British dominions

In conclusion, a word of commendation must be given for the excellent graphs which accompany the report the high character and able presentment of which reflect the careful selection of the Commissioners

---

THE LATE CHARLES MOON, M D EDIN —Dr Charles Moon, whose death has just occurred at his residence, Dundee, was born in 1843, and educated at St Andrews and Edinburgh Universities After qualifying, he started practice in Dundee, where he built up a large practice over a period of half a century He is survived by a widow, five sons, and two daughters

---

THE CONTROL OF VENEREAL DISEASES

The Bootle Scheme

THE scheme for the diagnosis and treatment of venereal diseases adopted by the Bootle town council has been approved by the Local Government Board and is now, we learn from Dr W Allen Daley, medical officer of health, in operation The salient features of this scheme are as follows —

1 Cases of venereal disease in their earlier and all communicable stages will be dealt with at the treatment centre (borough hospital), irrespective of their place of residence or their means 2 Mr W N Clemmey M R C S, honorary surgeon and radiologist to the hospital, has been appointed medical officer to the clinic, to be held at noon on two days a week, with facilities for attendance in the evening of persons unable to attend during working hours 3 Provision has been made at the hospital for microscopical examination of specimens from gonorrhœal cases Examination for spirochætes and Wassermann reactions will be undertaken by Professor L M Beattie at the University of Liverpool 4 Private practitioners may send patients to the hospital for blood to be taken for Wassermann reactions or for smears for the examination of spirochætes to be prepared 5 A report is posted to any private practitioner who sends a case for consultation 6 The Borough Hospital Committee receives £100 per annum for the services of its medical officer, and £25 for therapeutic agents for a period of six months Approved substitutes for salvarsan to be supplied by the Corporation The Hospital Committee reserves two beds to be used exclusively for persons suffering from venereal diseases the council paying £200 per annum, and an additional sum of 5s per night is paid for each person admitted for intravenous injection when the two reserved beds are already occupied 7 On personal request from private practitioners, reports on the previous treatment of patients will be furnished, but such reports will be given only with the consent of the patients 8 The scheme does not include the treatment of patients in places other than the hospital If the medical officer is called upon to attend patients in their homes a special fee will be charged

The cost of these arrangements for the first 12 months is estimated at £400, including the provision of a third bed in the hospital on 200 nights The medical officer of health is a member of the Liverpool Branch of the National Society for Combating Venereal Diseases and under its auspices lectures are being given for public instruction and enlightenment

Antimonial Treatment of Phagedæna and Syphilis

A paper by Dr D José Brotons, in the *Revista de Medicina*, on the treatment of phagedæna and syphilis by the intravenous injection of antimonial compounds (Los compuestos antimoniales por via endovenosa en el tratamiento del fagedenismo chancroso y en la sifilis) is of considerable interest The author gives clinical histories of five cases treated by this method three of soft chancres with phagedæna, one of ulcerating gummata, and one of hard chancre with very severe secondary symptoms and rapidly deepening cachexia In all these cases rapid improvement leading to cure of the condition was brought about by intravenous injections of doses of tartar emetic varying from 3 to 10 centigrammes and this after other methods of treatment had failed to arrest the morbid process Dr Brotons claims for antimony specific "anti spirillary" properties, and dissents from McDonagh's view that it acts merely by heightening the effect of iodine

Post Graduate Summer Courses in London.

Three hundred panel practitioners have already attended the courses of instruction given by Lieutenant-Colonel L W Harrison at the Military Hospital, Rochester row, London, S W 1, and arrangements are being made for holding further courses of instruction at the hospital during the forthcoming summer Many practitioners were compelled to forgo attendance at the winter courses through pressure of work The summer courses will be extended over a period of six weeks in order to give more opportunities for practical work Lieutenant-Colonel Harrison is prepared to give those practitioners who have already attended at the hospital a larger opportunity of attending practical demonstrations Applications should be made to the secretary of the London Panel Committee, 51, Chancery lane, W C 2

PARIS

(FROM OUR OWN CORRESPONDENT)

The Results of Operation in Purulent Arthritis

M Auvray has recently summarised at the Society of Surgery the operations performed by him during the war in 111 cases of suppurative arthritis of the large joints In every case definite purulent arthritis was shown to be present, sometimes unrecognised for several weeks after the infliction of the wound Only the immediate results of operation were available in regard to life and the preservation of the limb, the majority of patients having been lost sight of after healing of the wound The joints affected were the knee (34) the elbow (32), the shoulder (20), the ankle (12), the wrist (7), the hip (4) and the sacro iliac articulation (2) Eight patients died, a total mortality of 7 per cent Of the cases of purulent arthritis of the wrist, 7 were resected and all recovered Of the elbow 5 underwent arthrotomy only and all recovered, 9 in addition underwent secondary resection, and all of these also recovered, among the 18 cases in whom a more or less typical resection of the joint was of necessity performed at the onset one death occurred Of 20 cases of suppurative arthritis of the shoulder 2 were treated at the onset by resection and recovered, 18 of whom 1 died, underwent secondary resection For purulent arthritis of the ankle 12 operations were performed, of which 2 were amputations, all recovered with the exception of one of the amputation cases Of the 34 cases of suppurative arthritis of the knee 21 were submitted to arthrotomy resulting in 20 recoveries and 1 death, 4 were treated by resection, of whom 1 died and another, owing to symptoms of infection, was obliged to undergo amputation, in 9 other cases recourse to amputation proved necessary Out of a total, therefore, of 10 amputations there were 7 recoveries and 3 deaths Finally, in cases of suppurative arthritis of the hip, 4 resections gave 4 recoveries

Diphtheria in the Army

In a study dealing with the work of a diphtheria service Dr Louis Rue calls attention to the necessity of employing large doses of serum, especially under certain conditions This, although a cardinal point in treatment, is insufficiently recognised by some practitioners Under pre war conditions an average dose of 120 to 150 c c of serum in each case had reduced the total mortality to 3 45 per cent, and only a very small number of cases of diphtheritic paralysis were seen Dr Orticoni, who is an advocate of large doses of serum, found on his arrival at an infectious hospital base 20-25 and even 29 per cent mortality from certain sections of the front where doses of 50-60 c c daily were employed, while numerous cases of generalised paralysis resulted during convalescence Orticoni systematically introduced the method of large and repeated doses In cases of average severity he injected some 300 to 500 c c. in the course of the disease, in severe cases 700 to 1000 and even 1600 c c commencing with doses of 100 to 120 c c daily in two injections During a period of seven months he treated thus 208 cases of diphtheria, with only a single death Albuminuria became infrequent and only two or three patients passed at any time as much as 0 1-0 3 per cent of albumin Albuminuria is no contra indication to serum treatment, on the contrary if applied in the course of a case of moderately acute diphtheritic albuminuria the albumin rapidly disappears The only troublesome complications due to the serum were articular Urticaria was frequent affecting the abdominal walls or more generalised and attended with itching Paralysis was rare The serum should be continued two or three days after the false membrane has disappeared Larger doses were employed when the false membrane was greyish in colour or diffluent or when the surrounding mucosa was much affected Bleeding from the mouth or nose or blood staining of the mucosa around the false membrane suggest the advisability of large doses especially as the serum is not a negligible factor in increasing the coagulability of the blood The fear of anaphylaxis was found to be quite illusory as it could be avoided by a preventive administration of a dose of 1 to 4 grammes a day of calcium chloride and of injection of 1/4 of a milligramme of adrenalin M Rue indicates a symptom which might be disturbing to a doctor who had not been warned In certain cases a localised arthralgia occurs in the temporo-maxillary articulations, occasionally affecting the cervical and dorsal spine The resulting trismus and rigidity of the spine then suggest tetanus The fact of a previous injection of serum and the frequent co-existence of urticaria lead to a correct diagnosis

" Jigsaw " Autoplasty

M Morestin recently made a communication to the Academy of Medicine on a form of autoplasty which does not require any addition of foreign tissue At most it is necessary to take smallish strips from the immediate neighbourhood of the injury, for whereas deformity is often considerable the actual loss of substance may be very slight or even nil The tissue debris, scattered in irregular rents, shrivelled, or rolled up, are still generally living To turn these fragments to good account it is necessary to begin with the methodical removal of cicatrices scrupulously respecting all that remains of the healthy soft tissues Strips of mucosa are isolated without paying much attention at first to their method of disposal Dissection must be patient and complete, and the greatest possible mobility of the wound secured by dividing all adhesions At this stage the question arises of bringing together and reuniting the fragments Little by little the best arrangement is found the operator being guided all the time by the facts he ascertains In this form of reparative surgery no two cases are identical Sometimes the results obtained may be improved by touching up later but in many cases they are perfect from the first Jigsaw autoplasty has extensive indications in all injuries of the face, especially in mutilations of the lips and the cheeks General anæsthesia is hardly ever necessary

April 16th

URBAN VITAL STATISTICS

(Week ended April 7th 1917)

English and Welsh Towns —In the 96 English and Welsh towns with an aggregate civil population estimated at nearly 17 000 000 persons the annual rate of mortality was 17 3, against 16·9 and 18·0 per 1000 in the two preceding weeks In London, with a population exceeding 4 000 000 persons the death rate was 16 9 or 1 2 per 1000 below that recorded in the previous week among the remaining towns the rates ranged from 7·0 in Cambridge 7·7 in Oxford and 7 8 in Hornsey to 28 0 in Middlesbrough 28 5 in Great Yarmouth and 29·8 in Warrington The principal epidemic diseases caused 438 deaths which corresponded to an annual rate of 1 3 per 1000 and included 279 from measles 56 each from whooping-cough and infantile diarrhœa, 36 from diphtheria 8 from scarlet fever and 3 from enteric fever The deaths from measles showed a further increase compared with the numbers recorded in the 10 preceding weeks and caused the highest annual rates of 3 4 in Bolton 3 6 in Middlesbrough and in Sunderland and 6 3 in Dudley The 755 cases of scarlet fever and the 1297 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 40 and 80 below the numbers remaining at the end of the previous week Of the 5627 deaths from all causes in the 96 towns 191 resulted from violence The causes of 64 of the total deaths were uncertified of which 16 were registered in Birmingham 5 in Liverpool and 4 in Gateshead but only 1 in London

Scotch Towns —In the 16 largest Scotch towns with an aggregate population estimated at nearly 2 500 000 persons the death rate was equal to 16 9 against 16 2 and 17·9 per 1000 in the two preceding weeks The 386 deaths in Glasgow corresponded to an annual rate of 18·0 per 1000 and included 34 from whooping-cough 23 from measles 6 from infantile diarrhœa, 3 from diphtheria, and 1 from scarlet fever The 121 deaths in Edinburgh were equal to a rate of 19·0 per 1000 and included 10 from measles 8 from whooping-cough and 1 each from diphtheria and infantile diarrhœa.

Irish Towns —The 193 deaths registered in Dublin were equal to an annual rate of 25·9 or 3 4 per 1000 above that recorded in the previous week and included 20 from measles, 3 each from whooping cough and infantile diarrhœa, and 1 from diphtheria. The 190 deaths in Belfast corresponded to a rate of 25·2 per 1000 and included 8 from measles 5 from infantile diarrhœa, 2 from enteric fever and 1 from whooping-cough

BLINDED SAILORS AND SOLDIERS IN EDINBURGH —On April 12th Mr Barnes the Minister of Labour, visited the Scottish Blinded Soldiers and Sailors Hostel at Newington House, Edinburgh The history and work of the hostel were explained to him by Dr Burns and Mr Sommerville Grieve Mr W M Stone the superintendent, urging the disadvantage of centralising in London the training of blinded service men After inspecting the hostel and workshops Mr Barnes said that the work at Newington House ought to have a part in any general scheme of organisation for blinded service men

RADIATION IN MALIGNANT DISEASE

To the Editor of THE LANCET

SIR —I have read with much interest the paper on this subject by Captain A A Russell Green and *the leading* article in your issue of April 7th While in no sense wishing to decry the effect of radiation I cannot help thinking that you and your correspondent have formed a far too sanguine opinion on insufficient data I select for comment the treatment of rodent ulcer, a subject to which I have devoted long study, and which, in fact, forms the chief basis of *your correspondent's paper, for he tells us that only* two out of the 53 cases of ' neoplasmata," on which he reports, were not rodent Your correspondent bases his statistics, as far as I can follow them, on the mere healing of the rodent lesion, which I submit with confidence is a fallacious test Thus in Table IV we are told that 66 per cent of the traced cases were " healed " but the detailed analysis in which the duration of the observation is mentioned, in 24 cases which remained healed, more than half of these (13 to be exact) had been under scrutiny for less than two years Moreover, analysing the 25 cases of rodent ulcer in Table I , the most important from the author's standpoint, for these constitute the " traced healed cases," we find that only seven of the 25 cases had a longer duration than five years, a reasonable *conclusion from which data is that these were* comparatively early and small lesions, peculiarly amenable to treatment of any kind And this conclusion receives some confirmation from a consideration of Table II , "traced unhealed cases " for of 14 such, seven were of longer duration than five years, and in three of the remaining seven the duration is not specified The author therefore in his successful cases is probably dealing with small rodents as a rule

Now if we make mere healing of the lesion the criterion of success it is obvious that no treatment can compare with excision, for here 'healing" *is practically immediate and* complete But tested by the sole criterion which is of real importance, the ratio of recurrence, the argument for excision is greatly weakened for an examination of published statistics of the results of operation makes on the whole melancholy reading Two years ago in a paper on Rodent Ulcer contributed by me to the *British Journal of Dermatology*, reference was made to a table published by Butlin, in which of a large series of operated cases kept under observation for three years, recurrence took place in 63 per cent And I believe that that period of observation, although it compares very favourably with your correspondent's data, is far too short to allow of a considered judgment as to ultimate values of competing treatments

My personal opinion, expressed in the paper to which I have referred is that a method of far wider application (for it is at the disposal of every practitioner, which is certainly not the case with *radium) is the* method *of freezing* with carbon dioxide snow, a peculiarly valuable method in the small early rodent, and if practised at its first stages would I am confident materially lessen the *toll* of "unhealed" and inoperable cases —I am, Sir, yours faithfully,

Wimpole-street, W , April 17th, 1917 E GRAHAM LITTLE

To the Editor of THE LANCET

SIR,—In a leading article in THE LANCET of April 7th you advocate post-operative radiation in cancer You say ' However favourable a case may appear, no surgeon can be sure that he has removed every trace of malignancy , or, indeed, that he himself has not scattered malignant cells *over the field of operation* " (italics mine) If this was the worst that could happen *immediate post-operative* radiation might suffice to deal with it But who shall say to what part of the body these cells may not be carried in the blood stream ? I have for years been advocating *pre* operative, as well as *post* operative, radiation and perhaps you will allow me to quote from a contribution which I made to a discussion on ' Radiation in Cancer," which was opened by Sir Alfred Pearce Gould at the annual meeting of the British Medical Association at Brighton in July, 1913 Having pointed out that with modern X ray technique a depressant effect can be produced upon cancer cells long before there is any injury to the skin, I said —

> We know that whenever and wherever the knife is employed there is always a risk of disseminating malignant cells, which subsequently take root and flourish It is not to be supposed however that this colonisation is allowed to take place without opposition on the part of the invaded tissues Many of the would be settlers are no doubt slain before they are able to propagate their kind Some, nevertheless, usually escape, but if these *specially vigorous cells* were subjected to previous radio-therapeutic attack their chances of post-operative survival would be materially *lessened. A cancerous tumour* in an early stage presents an opportunity for X ray therapy which is never *repeated The enemy is concentrated in close order* and can be assaulted in force Every cancer cell which escapes removal will then be in a devitalised condition and in the presence of tissues whose resisting power has been artificially heightened

It has long been known that cancer grafts exposed to X rays will rarely " take " The present writer has in his *possession* pathological reports of cases of breast cancer which had been rayed for 3-4 weeks previous to operation. These reports stated that most of the cancer cells showed degenerative changes Moreover, American workers have recently proved that *raying of the wound surface into which a graft is to be put* reduces by one half the percentage of successful plantings [1] This furnishes experimental proof of another principle for which the present writer has contended—viz , that the effect of X rays in stimulating the healthy tissues to resistance is quite as important as any directly depressant action upon the cancer cells *Disregard of this principle leads to dire results*, as is sometimes seen in the extensive sloughing of normal tissues around a buried tube of radium

You rightly deprecate any attempt to pit X rays against radium or *vice-versa* May I point out, however, that any comparisons between X ray and radium effects are valueless unless exact details as to filtration, quality of ray, milliamperage in tube, distance from skin, time, number and spacing of exposures are all given For example, a " reaction " produced by soft unfiltered X rays has a significance quite other than a similar response produced by a very penetrating, heavily filtered Röntgen radiation In the one case the reaction is rapidly provoked and involves surface cells only , any malignant tissue lying even a few millimetres below the surface is unaffected In the other, response is more tardy, but the disturbance reaches to a depth of some centimetres The bearing of these facts upon liability *to recurrence is self evident*

I am, Sir, yours faithfully,
FRANCIS HERNAMAN JOHNSON

Cavendish square W April 8th 1917

⁂ Mr Hernaman Johnson states well known views —ED L.

THE TECHNIQUE OF LUMBAR PUNCTURE

To the Editor of THE LANCET

SIR,—I have noticed twice lately, while performing lumbar puncture for cerebro spinal fever, a phenomenon which might, if unrecognised, cause an error in diagnosis —

1 In the first case the needle (Barker's) was inserted into *the theca, and on withdrawing* the trocar cerebro-spinal fluid came out at the normal rate—i e , a drop every two or three seconds The needle was then pushed in a little further and the fluid came out in a jet under considerable pressure This occurred again in the same patient during a subsequent puncture

2 In this case the fluid came out at the normal rate, but inserting the needle farther did not increase the rate of flow As there were good grounds for suspecting cerebro-spinal fever, it was pushed on until felt to impinge on the body *of the vertebra, with still no* alteration in the rate of flow, even though the trocar had been reinserted It was then withdrawn a little and the fluid came off in a jet under pressure

In both cases puncture was performed under a general anæsthetic (C E)

If no *fluid* were *obtained* at all one would, of course, know the needle was blocked or that the theca had been missed, but when, on withdrawal of the trocar the fluid is found *to* flow at a normal rate, a *mistake* in diagnosis might easily occur, especially as in early cases the fluid is often not even opalescent and contains few or no organisms.

---

[1] See The Cancer Problem and the W ld War Pract March 1917 p 230

As I have seen no mention of this in the literature, but have had two cases showing it within the last month, I thought that—though a small point—it might be worth mentioning to you —I am, Sir, yours faithfully,

F A WILLIAMSON,

Major (temp Lieut Col) L. I Demetriadi relinquishes his temporary rank on ceasing to command a Casualty Clearing Station

Capt G J M Martin relinquishes his commission on account of ill health

DEATHS IN THE SERVICES

Surg Gen Sir William Taylor K.C B late Director General of the Army Medical Service on April 10th aged 74 at Windsor He joined the Army Medical Staff in 1864 and served in Canada and in India, where through the Burma campaign he was on the Staff of the Commander in Chief (mentioned in despatches) During the Chino-Japanese War he acted as Military Medical Attaché to the Japanese Army In the Ashanti Expedition 1895-6 he was principal medical officer (promoted to the rank of surgeon general) He was also principal medical officer of the expedition to Khartum in 1898, and was present at the Battle of Omdurman From 1898 to 1901 he was principal medical officer in India, and afterwards Director General of the Army Medical Service which post he held from 1901 to 1904 He was created C B in 1898 and K C B in 1902 He was a Knight of Grace of the Order of St John of Jerusalem in England and an honorary LL.D of Glasgow University

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Capt G B Bailey, Australian A.M C

Previously reported Missing now reported Killed

Capt S J Linzell, M C , R A.M C , qualified at Edinburgh in 1912, and held the appointment of house physician at the Royal Infirmary in that city, and was also an ex President of the Royal Medical Society of Edinburgh He obtained his captaincy in the R A.M C in March, 1915 and was on the staff as a Deputy Assistant Director of Medical Services The award of the Military Cross is announced in our "Honours List"

Died

Capt H A Lunn, R A M C , qualified at Glasgow in 1902, and practised in India before the war He joined the R.A.M C in 1914 and served in Gallipoli and elsewhere He returned to India at the close of last year, and died in hospital there of fracture of the skull brought about by an accidental fall

Capt J McC Orme, R A M C , qualified at Edinburgh in 1915, and thereupon joined up

Missing, believed Drowned (in the Hospital Ship "Salta" mined in the Channel)

Capt J R Gyllencreutz, R A M C , was a student at St Thomas's Hospital, London, and qualified in 1908 He held appointments at Wandsworth Infirmary, at Brentford Infirmary, and at the Royal Hospital, Portsmouth, and was in practice at Richmond, Surrey, prior to joining the R A M C

Capt G C B Hawes, R A M C , was a student at St George's Hospital, London, and qualified in 1893 He held house appointments at St George's, and was in practice at Pangbourne Berks (for which county he was a J P), before joining the R A M C

Capt T G S Hodson, R A.M C was educated at Newcastle on Tyne and at the London Hospital, and qualified in 1893 He was in practice in Wimpole street, London, at the time he joined the R A M C

Lieut J Naylor, R.A.M C , was a student at St Bartholomew's Hospital, London, and qualified in 1889 He held a surgical appointment at the Derbyshire General Infirmary, and was in practice at Tipton Green, Staffs, prior to joining the R A.M C in October last

Capt H G Smith, R.A M C , was a student at St Bartholomew's Hospital, London, and qualified in 1909 He held appointments at the Westminster Hospital and at the London Temperance Hospital, and for a time was resident surgeon at the Lord Derby War Hospital He was assistant medical officer of health and assistant school medical officer to the borough of Croydon, where he joined the R.A.M C in July last year

Wounded

Capt W L Cassells, R A M C

Capt W M Penny, R A M C , attached Yorkshire Light Infantry

Capt W N Gilmour, M C , R A M C , attached Royal Scots

Capt J R Kemp, M C , R A M C , attached Essex Regt

THE HONOURS LIST

The following awards to medical officers are announced —

Distinguished Service Order

Temp Lieut John Maximilian Hammond, R A M C , attached Devonshire Regiment

For conspicuous gallantry and devotion to duty in evacuating a large number of wounded under the most difficult conditions He was himself subsequently wounded and though both his feet were practically blown off he ordered his stretcher-bearers to carry away another wounded man first

Bar to the Military Cross

Temp Capt Ernest Emrys Isaac, M C , R A.M C , attached Royal Fusiliers

For conspicuous gallantry and devotion to duty He worked continuously under very heavy fire and was responsible for the successful evacuation of the wounded He set a splendid example of courage and determination throughout the operations

(The award of the Military Cross was announced in THE LANCET of Oct 28th 1916 p 770)

Temp Capt Patrick Joseph Lane, M C , R A.M C

For conspicuous gallantry and devotion to duty On several occasions he led out squads of stretcher bearers under very heavy fire and succeeded in bringing in many wounded men He set a splendid example of courage and determination throughout

(The award of the Military Cross was announced in THE LANCET of Dec 2nd 1916 p 958)

Capt Rudolph Albert Peters, M C , R A M C , attached King's Royal Rifle Corps

For conspicuous gallantry and devotion to duty He continually tended the wounded under very heavy fire He set a splendid example and showed an absolute disregard for his own personal safety He has on many previous occasions done fine work

(The award of the Military Cross was announced in THE LANCET of Oct 28th 1916 p 770)

Temp Capt John Caruthers Sale, M C , R A M C , attached Royal Fusiliers

For conspicuous gallantry and devotion to duty He displayed great courage in collecting and dressing the wounded in the face of a very heavy hostile barrage He set a splendid example to all ranks

(The award of the Military Cross was announced in THE LANCET of Dec 2nd, 1916 p 959)

Military Cross

Temp Capt Victor Thomas William Eagles, R A M C

For conspicuous gallantry and devotion to duty He organised and led search parties for wounded and worked continuously under very heavy fire for over 24 hours He set a splendid example of courage and determination throughout

Capt Norman Parsons Jewell, East African Medical Service

For conspicuous gallantry and devotion to duty He worked continuously for 62 hours and single-handed attended to over 100 wounded men He has on many previous occasions done fine work

Temp Lieut Charles Gordon Kemp, R A M C , attached Northern Regiment

For conspicuous gallantry and devotion to duty He worked unceasingly for two days under very heavy fire, and succeeded in evacuating a large number of wounded He displayed great courage and determination throughout the operations

Capt Stanley James Linzell, R A M C

For conspicuous gallantry and devotion to duty in superintending the evacuation of the wounded He continually visited the forward Battalion Headquarters passing under very heavy fire He set a splendid example of courage and determination throughout. (The death of this gallant officer is chronicled above)

Temp Capt Thomas McCosh, R A M C , attached Welsh Regiment

For conspicuous gallantry when his aid post was subjected to heavy shell fire for over three hours He, with absolute disregard for his own personal safety set a splendid example of courage and devotion to duty

Temp Surg William James McCracken, R N

For conspicuous gallantry and devotion to duty He continually attended to the wounded under very heavy fire He has previously done fine work

Temp Capt Herbert Walker, R A.M C

For conspicuous gallantry and devotion to duty He led his stretcher-bearers with great courage and determination for a period of 36 hours It was due to his energy and resource that a large number of wounded were evacuated under the most trying conditions

Capt Gladston Montague Hunt, Australian A M C

For conspicuous gallantry and devotion to duty He showed an absolute disregard of danger and set a splendid example to his stretcher bearers working with them over ground continually swept by heavy fire He worked for six consecutive weeks in a forward area in charge of an advanced dressing station

Capt Harrie Bertie Lee, Australian A M C

For conspicuous gallantry and devotion to duty in evacuating the wounded He set a splendid example throughout and worked continually under very heavy fire He has previously done fine work

DEATHS AMONG THE SONS OF MEDICAL MEN

The following sons of medical men must be added to our lists of those who have fallen during the war —

Capt V O Todd, Royal Lancaster Regiment, second son of Colonel O Todd, A M S

Brevet-Major H E Trevor, Northamptonshire Regiment temporary Lieutenant-Colonel Essex Regiment, son of Surg Gen Sir F Trevor, K C S I , C B , of Steeple Aston

Second Lieut A P Webb King's Shropshire Light Infantry, second son of Dr H P Webb

Second Lieut G S Spence, South Wales Borderers, younger son of the late Dr W J Spence, of Bedford

Second Lieut D N O'H Humphry Davy, Hampshire Regiment, younger son of Dr A Humphry Davy, of Bournemouth

MEDICAL MOBILISATION IN AMERICA

The important part which medicine has taken in the war has been generally acknowledged and appreciated When war was declared few people realised that it would develop on such a huge scale, or that the mobilisation of so large a proportion of the medical profession in the British Isles would be needed to supply the demands of the Army, yet in spite of these, the organisation of the medical profession has produced results which, when the true medical history of the war comes to be written, will redound to its credit. Coming into the war late America will have before her the vast medical experience of our own and other countries as well as her own gained in the prosecution of her beneficent Red Cross and other medical work on behalf of all the belligerents , but that she will also have to attend to her own domestic problems and that she has resolved firmly to do so is shown in a stirring leading article which appeared before the actual declaration of war with Germany In the February issue of *American Medicine* the writer says "Lethargy, indifference, inaction have given way to enthusiasm, application, and devoted service A nation of many component national factors has suddenly been welded into a homogeneous mass " In words which might equally apply to *our own country, America's failure to realise her responsibilities* as a Christian nation is pithily summed up thus "In the midst of prosperity and material success, the nation has grown careless, indolent, and wasteful National adolescence has been characterised by bombast, temerity, and extravagance " While recognising the need for the careful guidance of public opinion without jingoistic utterances and for patriotic inspiration free from cries for blood, it is pointed out that "If there must be war, let it be approached with grimness and determination as an unpleasant duty to be performed marshalling the best brains and brawn of the nation for the performance of the various duties for the successful determination of an early and permanent peace " The duties of the medical profession being protective and restorative and its services valuable to friend and foe alike, its thorough organisation is demanded and the article continues, 'On the brink of conflict, it is time to pause and contemplate the *constructive possibilities for true patriots How can* the medical profession best serve the nation? There should be not merely the development of new organisations requiring new machinery, large funds and scattered centres of interest, but the physicians of the nation, as a whole, should be organised as far as possible through the normal agencies now existent " From all this it seems clear that America, who remained neutral while she could do so without dishonour, has resolved now to enter the quarrel in a spirit of determination which should help to bring about the peace for which the whole civilized world is praying

THE WAR AND HOSPITAL SHIPS

Our columns this week contain two reminders of the merciless nature of the present naval warfare and the dangers to which the officers and men of the Royal Army Medical Corps are exposed on hospital ships When the *Salta* struck a mine in the Channel during bad weather on April 10th five medical men holding commissions as well as nine nursing sisters and 38 orderlies, are presumed to have been drowned Lieutenant-Colonel A G P Gipps's interesting surgical experiences on the *Asturias* remind us that that ill fated vessel, after successfully evading attack by a submarine in February, 1915, was torpedoed on the night of March 20th-21st last, when the casualties among the medical services on board included 11 dead 3 missing (a female staff nurse among them) and 17 injured Ten days later the *Gloucester Castle* was torpedoed, all the wounded on board being saved A new element has thus been introduced into the terrors of warfare and even the wounded man is no longer immune from further injury

Various Experiences in a Hospital Ship

The following experiences in a hospital ship, entitled 'Notes from H M H S *Asturias*," are recorded by Temporary Lieutenant Colonel A G P Gipps, R A M C (T C) —

This ship has been employed as a hospital ship by the War Office since the middle of August, 1914, of which time I have been in command some 17 months Some 350 to 400 operations have been performed on board, entirely by the staff of the Royal Army Medical Corps, which consisted of *six medical officers* besides myself

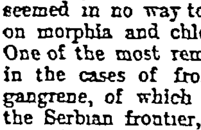
On one voyage some 40 cases of gas gangrene occurred, all in patients taken off Gallipoli during the fighting The gangrene spread so rapidly as to be almost visible in its advance, especially in the trunk None of the various treatments at all seemed to modify the attacks *Some lives were* seemingly saved by amputation high up where the extremities were attacked, even when tissues cut through at the time of operation were far from healthy The very high summer temperature—90° to 104° F —and the fact that there seemed to be millions of flies on board may have had something to do with its virulence and prevalence.

For cases of tetanus the various intrathecal injections recommended were used—presumably all the cases had been inoculated when wounded. The treatment of the cases occurring on board here, though pushed to the extreme, seemed in no way to control the disease, and we fell back on morphia and chloroform to relieve the severe spasms One of the most remarkable outbreaks of tetanus occurred in the cases of frost-bite with (1) moist and (2) dry gangrene, of which we received a number of cases from the Serbian frontier, where there were 23° of frost in the end of November and early in December The onset was quite sudden and was fatal within from 16 to 24 hours This was confirmed to me by other medical officers who dealt with these cases Treatment in no way affected them

The external iliac artery was tied three times for hæmorrhage high up from the femoral in Scarpa s triangle.

A few short notes of two cases of special interest are appended

CASE 1 —Private, received from the trenches on Gallipoli He was suffering from a wound just to the left of the sternum in the fourth intercostal space partially perforating the sternum On the fifth day after his arrival on board a severe hæmorrhage occurred which was temporarily controlled by plugging whilst the patient was being conveyed to the operating table On removing the plug the bleeding recurred with great violence The wound being deep and small, I turned up the left breast to expose the intercostal muscles The bleeding point could not be distinguished, but could be partially controlled by digital pressure At last after several attempts, a pair of pressure forceps caught a portion of the severed vessel and it was then possible to open up the wound and the bleeding was controlled by the further application of forceps. On passing the finger behind the sternum the nickel casing of a bullet was found lying on the pericardium it was squeezed flat into a knife-edge and the heart's action was sawing it up and down, and had divided the internal mammary artery I removed the bullet casing (see figure), tied the internal mammary in the second interspace and removed the controlling forceps The breast, which had been reflected was replaced and stitched in place The patient had no further trouble



Showing size and shape of bulle casing removed from pericardium

CASE 2 —Private, received on board from the fighting in Serbia He was in a very bad way the left patella had been shattered some days previously, and only some fragments remained The wound in front of the knee-joint was as large as my hand Temperature 104° F , pulse 120 The wound was cleansed dressed and the leg temporarily put up on a back splint with foot piece The next day, the patient being worse with severe pain and the temperature over 104 he was placed on the operating table Both synovial pouches in front of the joint and the whole of the joint itself were found full of stinking pus and dirt I laid the whole joint widely open and flushed and washed out with sterile saline the synovial pouches and the rest of the joint and removed the remains of the patella A drain of broad rubber tape was placed on the outer side of the knee, draining through an opening made on the outer side of the popliteal space Finally with a view of sterilising if possible the entire joint it was thoroughly flushed out with ether, the ether being allowed to remain in place some two minutes each time then squeezed out and replaced with fresh this was repeated some half dozen times That night the temperature fell to 99 4° and in the morning was only jus above normal The wound throughout was dressed with dry sterilised gauze, wrung out in sol hyd biniod 1 in 1000 made practically dry The drainage tape was removed at the end of 14 days From the day of the operation the patient never looked back—from being almost a skeleton he became fat and healthy The granulating wound which was of course very extensive after six weeks I grafted in about 14 places of which 11 grafts took When healed over the leg was put up in plaster-of Paris covering the knee joint and extending 6 inches above and below the joint The patient was daily carried on deck and within three months of coming on board was able to walk about the ship with the nominal assistance of a walking stick which however he used but little There was in spite of the loss of the patella a certain amount of power of extension left

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND —At the quarterly examination in Practical Pharmacy held on April 12th the following candidates were successful —

Ernest Horace Bryant and William Barnes Buer Guy s Hospital Horace Braithwaite Bullen Cambridge University and St Bartholomew s Hospital Charles Grinling Bunn Cambridge University and Charing Cross Hospital Benjamin Young Harper Christmas Middlesex Hospital John Rudolph Cox Guy s Hospital Edward Ernest Elt Charing Cross Hospital Mendel Gourevitch London Hospital Norman Bernard de Medina Greenstreet Cambridge University and St Thomas s Hospital Oliver Halstead and Walter Ralph Gill Hearnden Guy s Hospital Gilbert Rashleigh Hull St Thomas s Hospital John Powell Jones Jenkins University College Cardiff and Westminster Hospital Montagu Horace Jupe, London Hospital Salomon Kadinsky Brussels King s College and Westminster Hospital Charles William Lakin Birmingham University Archibald Magill Guy's Hospital Ahmed Othman King's College Gerald Richardson Sharp London Hospital Jacques Spira, St Thomas s Hospital Doris Kathleen Shuttleworth Leeds University Thomas Cowley Stephen Manchester University Ronald Henry Tasker Bristol University Joseph Stanley Thomas London Hospital John Henry Tighe Birmingham University Jose Victory Guy s Hospital and Arthur Winfield Cambridge and Liverpool Universities

* Pathology completing examination

† Medical Jurisprudence and Hygiene completing examination.

Part II B A O , Midwifery and Gynæcology —Edward D Arcy McCrea Alexander Richard Barlas Bryan Austin McSwiney Margaret Wolfe *Percy Crowe Parr* Joseph Roland Brennan Hastings Harley Molloy Thomas Tabuteau Paul Herbert Shelly Smith Patrick Casey Thomas Hugh Robinson McKiernan, and John James Keatley

B Ch Surgery —James Arthur William Cullen (high marks) George Bernard Shaw Henry Banks, Henry James Rice Paul Herbert Shelly Smith and Hirsh Brill

M B Medicine —Alexander Richard Barlas (high marks) *Edward* D Arcy McCrea (high marks) James Carter O Gilvie, Paul Herbert Shelly Smith William Frederick Wicht Olive Gertrude Blackham *Pieter Johannes Swanepoel.* Willem Petrus Lubbe Gilbert Marshall James Arthur William Cullen Thomas Edward Hill and Hastings Harley Molloy

Dental (B Dent Sc.) —John Henry James Stuart

DIPLOMA IN PUBLIC HEALTH (D P H)

Part I Chemistry, Meteorology, and Bacteriology —Thomas Kirkwood and Bagenal Harvey Mellon

Part II Sanitary Engineering Vital Statistics Hygiene and Epidemiology —Bagenal Harvey Mellon.

LITERARY INTELLIGENCE —Mr Heinemann announces the immediate issue of a treatise on Malingering by Dr A. Bassett Jones and Dr R Ll J Llewellyn.

THE Council of the Medical Society of London have awarded the Fothergillian medal for 1917 to Sir Leonard Rogers, I M S , C I E , F R S , of the Medical College, Calcutta, in consideration of his work on Dysenteries, their Differentiation and Treatment

THE Society of the Swedish *Physicians* (Svenska Läkaresällskapet) has elected Colonel Robert Jones, C B , Inspector of Military Orthopædics, to be a foreign member of the society The honour was conferred at the instance of Dr Haglund, professor of orthopædics, Stockholm, supported by the professor of surgery, Dr John Berg, and by Dr Henning Waldenstrom, lecturer on orthopædics

ROYAL SOCIETY OF ARTS —The following lectures will be delivered during April and May on Wednesday afternoons at 4.30 —April 25th, Sir Francis Fox on Flour and Bread, May 2nd, Mr J C Shenstone on Herb Growing in the British Empire, May 16th, Sir C Arthur Pearson on the Blind Sufferers from the War and their Future Employment.

PAYMENT FOR THE DOMICILIARY TREATMENT OF TUBERCULOSIS IN BELFAST —A Belfast correspondent writes —"Three members of the city council of Belfast—Dr J D Williamson, Dr R Thomson and *Dr* S Allworthy —have resigned in order to make their position clear in connexion with payments made to them by the council for the domiciliary treatment of pulmonary tuberculosis (see THE LANCET, April 7th, p 556) Probably when the new Municipal Bodies Emergency Act is passed the whole question will be put upon an entirely *different* footing"

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to THE LANCET *Office directed to the Sub-Editor not later than 9 o clock on the Thursday morning of each week such information for gratuitous publication*

BOYD R. M. M B., Ch B Aberd has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Braemar District of the county of Aberdeen

FISHER, H P M B Camb., Certifying Surgeon under the Factory and Workshop Acts for the Atherstone District of the county of Warwick

HIGGIN ROBERT FRANCIS B.A. M D., B C Cantab., L.R.C P., M.R.C S., Acting Medical Officer to the Newton Abbot (Devon) Union Workhouse

PROCTER, J A., L S A. Lond Certifying Surgeon under the Factory and Workshop Acts for the Lydd District of the county of Kent

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor

ANGLO-RUSSIAN HOSPITAL, 32, Victoria-street S W —Two Surgeons for Russia.

BARNSLEY BECKETT HOSPITAL.—Honorary Staff for Out patients (Two Vacancies)

BARROW IN FURNESS NORTH LONSDALE HOSPITAL.—Second House Surgeon Salary £250 per annum with board &c

BETHNAL GREEN INFIRMARY Waterloo House, Waterloo-road E —Assistant Medical Officer Salary at rate of £250 per annum.

BOLTON INFIRMARY AND DISPENSARY —Second House Surgeon. Salary £200 per annum, with board &c.

BOURNEMOUTH, ROYAL VICTORIA AND WEST HANTS HOSPITAL, Boscombe Branch.—House Surgeon. Salary £125 and extras, with board &

BRADFORD CITY EDUCATION COMMITTEE.—Temporary Assistants to School Medical Officer

BRISTOL ROYAL INFIRMARY —House Physician and House Surgeon. Salary at rate of £120 per annum with board &c.

BURNLEY VICTORIA HOSPITAL.—House Surgeon. Salary £160 per annum with board &c.

BURNLEY UNION —Resident Assistant Medical Officer Salary £300 per annum with rations, &c

BURY INFIRMARY —Junior House Surgeon. Salary £150 per annum, with board &c.

BURY AND DISTRICT JOINT HOSPITAL BOARD —Assistant to Medical Superintendent. Salary £250 per annum, with board, &c.

CHESTER ROYAL INFIRMARY —Assistant House Surgeon Salary £150 per annum with board &c

CLINICAL RESEARCH ASSOCIATION LIMITED Watergate House, York Buildings Adelphi W C —Medical Man or Woman for service in Laboratories

GREAT NORTHERN CENTRAL HOSPITAL, Holloway road, N —Resident Medical Officer Salary £200 per annum with board &c

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST Brompton. —House Physician for six months Salary 30 guineas

HUDDERSFIELD STORTHES HALL ASYLUM Kirkburton, near Huddersfield —Locum Tenens Salary £7 7s per week with board &c.

KENT COUNTY COUNCIL.—Tuberculosis Officer Salary at rate of £500 per annum &c.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon Salary £125 per annum with board &c.

MANCHESTER, ANCOATS HOSPITAL.—House Physician Salary £200 per annum with board &c.

MANCHESTER, BAGULEY SANATORIUM FOR TUBERCULOSIS —First Assistant Medical Officer unmarried. Salary £350 per annum, with board &c

METROPOLITAN HOSPITAL, TUBERCULOSIS DISPENSARY FOR THE METROPOLITAN BOROUGHS OF HACKNEY AND STOKE NEWINGTON Kingsland road E —Temporary Medical Officer Salary at rate of £500 per annum

NETLEY WELSH HOSPITAL.—Medical Officer for Pathological Department Salary £400 per annum with board &c

NEW HOSPITAL FOR WOMEN Euston road N W —Female Assistant Physician and Assistant Surgeon.

NEWCASTLE UPON TYNE ROYAL VICTORIA INFIRMARY —Four House Physicians Five House Surgeon Two Accident room House Surgeons House Surgeon to Aural and Ophthalmic Department House Surgeon to Gynæcological Department, House Surgeon to Skin and Venereal Department, House Surgeon to Out patient Dressing Department

NORTHAMPTON GENERAL HOSPITAL.—House Surgeon. Salary £200 per annum with board &c Also Two Junior House Surgeons Salaries £150 per annum with board &c.

NOTTINGHAM GENERAL HOSPITAL.—Two Assistant House Surgeons for six months Salary at rate of £250 per annum each board &c

[illegible] EDUCATION COMMITTEE.—Female Assistant School Medical Officer Salary £300 per annum

PLAISTOW FEVER HOSPITAL, London E —Female Temporary Resident Medical Officer to take Clinical Charge of the Dagenham Sanatorium for Pulmonary Tuberculosis Salary at rate of £250 per annum and all found

[illegible] ROYAL INFIRMARY —Resident Medical and Surgical Officer Salary £1[illegible]0 per annum with board &c

THE Chief Inspector of Factories Home Office London S W , gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Annan at Brampton and at Tamworth.

Births, Marriages, and Deaths.

BIRTHS.

KELLOCK.—On April 15th at 2 Upper Wimpole-street, the wife of Thomas H Kellock M C F R C S of a son

MARSHALL.—On April 10th, at Cambridge, the wife of Russell H. S Marshall R.A.M C of a son

MCKELLAR.—On April 17th at Chester-le-Street, County Durham the wife of Dr W A. McKellar of a son.

WATT —On April 9th, Dorothy the wife of James Watt M.D., Medical Superintendent Odsal Sanatorium Bradford, of a son

WILSON —On April 12th at Devonshire-street W the wife of Alex Wilson M D Captain R.A M C of Crest House, Putney Bridge-road S W of a daughter

MARRIAGES

ACKLAND—BUCKLE.—On April 10th at St. Mary Abbots, Kensington, William Robert Ackland Major R.A.M.C T to Georgina, widow of Henry Buckle Burma Commission (retired)

BELL—CLAYSON —On March 19th, at St. Andrew s Farnham Surrey William Ker Bell, Captain R.A.M.C to Katherine B Clayson of Eastleigh Farnham.

EGAN—MASON —On April 11th at St. James s, Piccadilly W Staff Surgeon Percy Blackwood Egan M.D R.N., to Rosalie Stella youngest daughter of the late Mr O A. T Mason D L R.I C of Grangefoyle Strabane, and of Mrs Mason Bray Ireland

GRAVES—PADDAY —On April 11th at St Barnabas, Kensington, W George Henry Fullarton Graves, Temporary Lieutenant, R.A.M C to Linda Maud of Holland road, Kensington W eldest daughter of the late Reginald H Padday of Singapore

WILSON—HODGE.—On April 12th, at Hyndland Church Glasgow George Hanswell Wilson M B. Ch B., to Amy Lawrence, youngest daughter of Mr and Mrs. William Hodge, Montgomerie-drive Glasgow

DEATHS

HAWES —On April 10th through the sinking of H.M H.S *Salta* Godfrey Charles Browne Hawes of Pangbourne Berks Temporary Captain R.A.M C J P M R.C S., L R C.P L.S A.

JONES —On April 13th after a short illness at his residence 16A Abercromby-square, Liverpool aged 53 years Hugh Richard Jones, M D

KING —On April 11th, at S Cyprian s Stratton Cornwall, John King M R C S J P in his 73rd year

LUNN —On March 5th at a hospital in India, as the result of an accident Captain Henry Anderson Lunn, R A.M.C

POTTER.—On April 9th 1917 suddenly at Brighton Henry Perry Potter M D F R.C S D.P H., of Kensington Infirmary for 37 years Medical Superintendent aged 63 years

RUTHERFORD —On April 11th at St Thomas s Hospital, London Leonard Trevelyan Rutherford M A. M B Cantab aged 29

TAYLOR.—On April 10th, at Windsor Surgeon-General Sir William Taylor K.C.B late Director General Army Medical Service aged 74 years

THOMPSON —On April 9th at Grenville House Bideford Charles Sinclair Thompson M B

N.B.—A fee of 5s is charged for the insertion of Notices of Births, Marriages and Deaths

DOCTORS OF MILITARY AGE THE SQUABBLE AT LETTERKENNY —An Irish correspondent writes "An extraordinary scene occurred at a meeting of the Letterkenny Board of Guardians on April 13th It will be recollected that at a recent election for dispensary doctor there were two candidates, Dr W N Walker and Dr J P McGinley The latter was elected but as he was of military age the Local Government Board refused its sanction The guardians adhere to their decision and an amusing situation has arisen Dr McGinley treating patients at the guardians' dispensary and Dr Walker at his private surgery the tickets authorising each doctor to attend patients being signed by the guardians according to their view as to who is really the legally appointed doctor At the last meeting of the board when the pay sheets of the doctors were submitted for the chairman s signature the first pay sheet was snatched from him and he himself was forcibly ejected from the chair A wild scene of disorder followed "

Notes, Short Comments, and Answers to Correspondents.

MEDICAL NOTES IN HISTORICAL MANUSCRIPTS THE STUART PAPERS

We give below the concluding excerpts from Part VI of the Stuart Papers The first and second instalments appeared in our issues of April 7th (p 558) and 14th (p 594) respectively

Health of James III —Operation for Fistula

Pope Clement XI to James III —1716 May 19 Santa Maria Maggiore, Rome —Granting him permission on account of his health to eat meat eggs &c, on fast days with an exception as regards meat in Holy Week

The Duke of Mar to Lieut. General Dillon —1716, Oct. 4 —' James has been a good deal out of order for some time with the piles and though he be now in a fair way of recovery, I hope yet he is not so easy that he can write

Queen Mary to the Duke of Mar —1716 Oct 10 — 'As soon as I had read your letter I sent for Mr Inese who you know may be trusted and consulted with him which way wee should take to gett a good chirurgien to send to Avignon without letting so much as himself know who he went for wee resolved to employe Dr Maghie in this affair since I dare not appear in it myself he is honest and is acquainted with several good chirurgiens and I hope will keep the secret which I earnestly recommended to him I was in hopes all this would have been done this morning and ther was a chair ready with post horses but an houre ago Dr Maghie brought me the enclosed from Mr Inese and gave me an account of all he has done in this affair, which I made him put in writting and here I send it you but I will not seal up this letter till 6 o clock, by which time Dr Maghie has promised to lett me know positively whether Guerin will go and what day If wee cannot prevail with him wee must take one that he will answer for nay, he says he cannot go himself without consulting Marechal of whom he mucch depends so that wee cannot hinder that, but Dr Maghie assures me that non of them thinks any mor than that it is a man of quality com out of England that hides himself and will not be known to any whicch I hope they will still beleeve and suspect nothing els' In all the trouble I am in which you may much easier imagine than I can express it it is a comfort to me to have you near the King I am confident you will be of great use to him in persuading him to be exact in performing the doctors and chirurgiens prescriptions and in keeping company and businesse from him

The enclosure referred to in the above is as follows —

L Inese to Queen Mary —1716 Saturday Oct. 10 10 A M — Your Majesty cannot imagine what difficulty there is to find an able surgeon that will go so far on such short warning they being all engaged with patients they cannot quit on a sudden I thought it necessary to send Dr Maghie to inform you of what they say he having spoke with them and all of them being of opinion that there can be no danger in some days delay The courier that came up has been very indiscreet having told everybody he was sent by the king to your Majesty You will be pleased to give your orders to Dr Maghie who has taken great pains last night and this morning

Statement by Dr John Maghie — As soon as I received the Queen s orders last night from Mr Inese I went immediately to Thibaut, the chief surgeon in the Hotel Dieu one famous in the case He told me it was impossible for him to make the journey on any account He recommended Collignon with whom I was early this morning and likewise with Monsr Arnaud both so engaged that they cannot go Afterwards I went to Guerin one as expert as any of the others He likewise cannot go immediately but I have hopes to prevail with him in a few days Observe that Thibaut Arnaud and Guerin agree that there can be no danger in delaying the operation for some eight ten, or twelve days—nay Arnaud said fifteen or three weeks However no time shall be lost in sending one as soon as possible in whom one can have entire confidence"

I Inese to Queen Mary —1716 Sat Oct. 10 4 o clock — 'Dr Maghie has just come in and desires your Majesty to be informed that he has been again with Dr Guerin who now thinks he can part from this in three days but he must first speak with M Marechal on whom he depends He will give his positive answer to-morrow As most of such people have an eye to their own interest and it cannot be told them who the person is they are to trust this M Guerin made a bargain what he is to have as he must be absent three weeks or a month and lose his practice which is considerable in the meantime The doctor thinks he should be offered 3000 livres to be secured him when the operation is over and all his charges going and returning If you approve pray let me know and the offer shall be made to-morrow when I see him or in the manner you think fit, but too great an offer might probably give him suspicion who the person is He may be told that if all succeeds he shall have a recompense over and above"

L Inese to the Duke of Mar —1716, Oct 13 Paris.—' You will receive this from M Guerin who is by all esteemed one of the ablest chirurgeons of Paris and of the greatest experience in the operation he now goes about, and has been always successful in all he has undertaken He is an élève of the famous M Marechal and employed by him in the most difficult operations of this kind I have given him assurance of 3000 livres besides all his charges and of a reasonable present besides when the operation is happily over I dared not offer more for fear of giving him suspicion nor could I offer less being informed he gains sometimes 3000 livres in a month without going out of Paris He only knows it is a person of quality he is to treat who will not be named for fear of alarming his relations but suspects it is either Ormonde or Mar

Queen Mary to the Duke of Mar —1716 Oct. 17 *Chaillot.*— 'I dare not send the enclosed to the King for fear the operation should be over before this comes to Avignon but I dare not omitt sending it to you that you may know what is said and take your measures accordingly The King and the Duke of Ormond know this fair lady [Olive Trant] very well She certainly means well but one must not believe all that is sayd .. I pray God direct you and the Duke of Ormonde to do what s best, but if the operation be not made the King should be informed of this and decide himself

The enclosure referred to in the foregoing is as follows —

Olive Trant to Queen Mary — The surgeon Marechal s *nephew* who is gone to the King is reputed to be very stupid Chirac, whom I have just seen tells me there is one Barancy a surgeon now living at Montpellier who is one of the most able in France and it is important that he should attend the King with Guerin, who is no so able as might be wished There is still time to send Barancy Your Majesty will have the kindness not to quote Charac as to what I have said about Guerin but he is willing to be [quoted?] about Barancy s ability

The Duke of Mar to Sir H Paterson —1716 Oct 21.—"When I tell you that James was this morning cut of a fistula *in ano* you will not wonder that I am in a hurry having letters to write every where upon it I thank God it is well over and he out of danger He endured the operation with all the fortitude in the world I was by and was grieved with the King but charmed with the spirit he showed The operation lasted about five minutes and was very well performed by Guerin a chirurgeon we had sent for from Paris. He had ten cuts of the knife and scissors but the wound is not deep. Both the doctor and chirurgeon assure us that there is no further danger and he is as calm and tranquil as possibly can be expected, without the least appearance of any fever They will report him dead I doubt not. who wish it; therefore it would do well that you could have a right account of it put into your newspapers Since it was God s pleasure he should have this illness it has not taken him in an unlucky time for it will give him and his friends time to look about them before they be sent a travelling if that must needs come. It will be two months before he be in a condition to go anywhere and sure they will not be so barbarous as to force him to it before he be safe, and before two months expire tis hard to tell what may cast up (Further letters show that James s recovery was slow, but without complications)

The Duke of Mar to Monsieur Stiernhock —1718 May 24 —"My master [James III] had been a little indisposed for a few days before he had the news of the Queen s death and had some symptoms of an ague so that account came very unseasonably for that and many other reasons His indisposition was but slight occasioned as far as we can judge by the sudden change from excessive heat to very cold which had the same effect on more of us, but I hope a few doses of the bark will carry it off

James III to his cousin the Duchess of Hanover —1718 Friday May 27 —"A slight recurrence of tertian fever prevents me from writing to you with my own hand"

James III to the Prince De Vaudemont —1718 June 26, Urbino.—"I should have long since sought some consolation from you had I not been for two months prostrated by a fever which has prevented me from the least application

Lieutenant General Dillon to the Duke of Mar —1718 Saturday June 4 — I am much troubled to find the King s ague continues I hope it will soon be over and beseech the Almighty to comfort him in his just affliction Nairne advised me of the King s taking a vomit 7 May and of his being somewhat weak two days after No violent remedy can be good for his constitution and it is not very usual to make an experience on persons of his rank it being a nice point and not practised except in great extremities The doctor ought to know best, though it be very sure his prescription will meet with little or no approbation among the physicians here

COMFORTS FOR THE FORCES

Mr John Penoyre, writing on behalf of Sir Edward Ward, Director General of Voluntary Organisations, says that last year the interval between the last cold night of spring and the first chills of autumn was overestimated, and that this year a vast store of sweaters, mufflers, helmets, mittens, and socks will be wanted by August 1st These should be sent, when the time draws near, either to the D G V O's Depôt, 45, Horseferry road, S W 1, or to Mr Penoyre, 8, King's Bench Walk, Inner Temple E C 4 Easily knitted patterns of any of the articles mentioned can be had free on application

ECONOMY IN RUBBER GLOVES

To the Editor of The Lancet

Sir,—Referring to a letter appearing in your issue of March 31st on the above subject I have examined these repairs, and think that, from the surgeon's point of view, they are satisfactory From the public point of view it would appear that the saving to be effected certainly warrants an immediate trial of this method by all hospital authorities, and in particular by the Royal Army Medical Corps controlling the military beds

I am, Sir, yours faithfully
W Arbuthnot Lane

Cavendish square W April 9th 1917

To the Editor of The Lancet

Sir,—In your issue of March 31st last appeared a letter on the repair of surgical rubber gloves by a new process The amount spent on these gloves is understated, some hospitals must spend £500 or more a year on them I have used gloves repaired in the manner described for some years at the Leicester Royal Infirmary The puncture repairs are so small as to be almost unnoticeable Of course, when rubber has become brittle from repeated sterilisation at a high temperature any repair is useless A fair proportion of gloves, however, are injured whilst the rubber is still in good condition, either by puncture with the needle or by manipulation (more particularly in bone operations), or even by pulling them on roughly Most of these latter are capable of repair The proportion repairable, however, must vary very considerably depending on the class of operation, &c Many hospitals repair their own punctures with rubber solution, even they, however, would be well advised to try the Leicester method for larger tears.

I am, Sir, yours faithfully,
HENRY J BLAKESLEY, F.R C S Eng,
Major R.A.M C T. Senior Honorary Surgeon Leicester
April 14th 1917 Royal Infirmary

THE CHEMICALISING OF CORPSES

THERE appear to be good reasons for believing that the Germans are utilising the bodies of their dead by committing them to a chemical treatment which, for one thing, yields fat and for another, a nitrogenous powder which serves so it is stated, to enrich pig feed, and, yet for another, the mineral phosphate of the bones to be used as a fertiliser in the field The recovery of fat by what may appear to be a gruesome policy means, of course, a source of material for the making of glycerine and its nitro-derivative The total amount of fat in the human body varies immensely, but it may be said to range from 2·5 to 5 per cent of the body weight It is easy to see that in a period of heavy casualties this method for the disposal of the dead will yield a very material amount of glycerine Thus, a thousand bodies at an average weight of 10 stone (140 lb) would yield on an average of a 3 per cent. basis of fat per body weight about 2 tons of fat capable of being turned into a tenth of its weight of glycerine—i e, 4 cwt As the published number of killed far exceeds this the output of glycerine may have been increased proportionally not to mention the soap incidentally produced The dividends of the enterprising company known as the Kadaververwertungsanstalt (Corpse Utilisation Establishment) may, according to this calculation, be quite satisfactory to the directors and shareholders, enabling them to face criticism with complacency

PROLONGED NASAL FEEDING

To the Editor of THE LANCET

SIR —A man was admitted to this asylum in 1885 and has just died here at the age of 81 For several years he had to be spoon fed after his admission, but for the last 21 years and 7 months he was fed three times daily through the nasal tube He enjoyed excellent health until the last three months, when his health began to fail I never heard of his taking a drink of water for all these years but during the last two days of his life he took warm milk from a fellow patient but not from an attendant. The following was his daily diet scale —

Breakfast One quart of milk, two eggs and 1½ oz. of sugar Dinner One quart of beef tea, or beef fluid made from bovril or oxo and one or two potatoes, mashed fine enough to go through the nasal tube Supper One quart of milk, one egg and 1½ oz. of sugar

Is this a record in prolonged nasal feeding?

I am, Sir yours faithfully,
E E MOORE M D Dub,
Medical Superintendent
Donegal District Asylum Letterkenny April 12th, 1917

HEALTH OF ST LUCIA.

A REPORT on the colony of St Lucia for the year 1915–16 has just been presented to Parliament From this it appears that the population is estimated to consist of 24,115 males and 28 167 females—total 52 282—a slight increase as compared with the previous year The birth rate for 1915–16 was 33 per 1000 of the population and the death rate 19 7 per 1000 There were two deaths from snake-bite and one from scorpion bite All the medical officers report the health conditions of the year to have been favourable The hookworm campaign inaugurated at the expense of the International Health Commission continued its work under the direction of Dr Stanley Branch, a local district medical officer seconded for this purpose and side by side with this campaign the Government is adopting measures for the improvement of the sanitary conditions in the colony generally The Victoria Hospital at Castries is the one general hospital for the colony and the daily average number of patients was 70 The construction of a wing for private paying patients has been commenced Small buildings are provided in the out-districts at Soufriere Dennery and Vieux Fort which are used as casualty hospitals for accident and emergency cases and there are visiting stations at various points where medical officers attend regularly on fixed days for the treatment of out-door cases of sickness

The yaws hospital which is in the vicinity of the Poor Asylum at Malgre-toute had a daily average of 43 2 patients The voluntary influx of patients for treatment with arsenobenzol continued unabated during the year and [illegible] cases were treated The medical officer in charge Dr A F Hughes reports that up to date he had treated 1188 cases and that out of this number there had been 63 cases of recurrence of the disease In this latter connexion the medical officer refers to the difficulty of his distinguishing between bona fide recurrences and cases of reinfection

SPRUE

REFERRING to the annotation which appeared under the above heading in our issue of last week, Mr John Ward, of the Crookes Laboratories, states that the use of collosol argentum in this disease was mentioned in papers read before the annual meetings of the British Medical Association in 1913 and 1914 notably by Mr James Cantlie Further experience, he adds, indicates the alternate use of collosol argentum and collosol iodine—of course, by internal administration

---

Recruits —The fees should, in our opinion, be included in our correspondent's return for income-tax, as the profit arising therefrom can scarcely be defined as profit arising from a single or casual transaction outside the usual scope of the profession The point might be put before the district surveyor of taxes, whose advice is usually sound and impartial.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot undertake to return MSS not used

Offices- 423, STRAND, LONDON, W C 2

MANAGER'S NOTICES

ALTERATION IN THE PRICE OF "THE LANCET"

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET Commencing with the new year, the price was raised to *8d* The rates of subscription remain as revised in October

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand London, W C 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with *none of whom have the Proprietors* any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

TO COLONIAL AND FOREIGN SUBSCRIBERS

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied

Communications, Letters, &c., have been received from—

WAR SURGERY OF THE ABDOMEN

Delivered before the Medical Society of London

BY CUTHBERT WALLACE, B S LOND,
F R C S ENG C M G,
SURGEON TO ST THOMAS'S HOSPITAL CONSULTING SURGEON BRITISH EXPEDITIONARY FORCE.

LECTURE III[1]

Delivered on March 23rd, 1917

WOUNDS OF PARTICULAR ORGANS (*continued*)

Large Intestine

Frequency —The colon was perforated in 258 cases among 965 operations

Associated injuries —The small intestine is the organ most frequently injured with the great gut. The stomach goes with the transverse colon the spleen and kidney with the splenic flexure the liver and right kidney with the hepatic flexure. In speaking of side to-side wounds, we have given some instances of curious injuries and one may recall here a case where the left kidney and the posterior surface of the ascending colon were the only lesions found.

The injuries of the large intestine are really similar to those of the small gut. The differences that are to be noted are due to its larger size the absence of coils the absence of mesentery and to its proximity in some portion of its extent to bone

1 *The large size of the tube* leads to a preponderance of tears or perforations, but instances are met with in which the whole lumen is completely divided, and this happens both in the fixed portion and in that endowed with the mesentery This complete division is I think, due to a collapsed condition of the intestine when it may be as is well known but little bigger than the small intestine

2 *Absence of coils* —This means that multiple injuries are not common and when they occur are not so numerous as in the small intestine The multiple injuries are found at the bends In one case which may be mentioned there were six perforations—two in the ascending two in the hepatic flexure and two in the transverse colon In another case there were three wounds in the cæcum and ascending colon and two in the hepatic flexure.

3. *The absence of the mesentery* over a great part of its course means a frequent occurrence of retroperitoneal wounds These are difficult to find and are largely responsible for the heavy mortality The partially covered portion of the small intestine—namely the duodenum—has likewise a very large mortality

4 *Proximity to bone* —This leads to wounds of the cæcum the two vertical colons and the pelvic loop by spicules of bone and as has been pointed out, these injuries are apt to be overlooked because the perforations in the peritoneum are no conspicuous

Infarction —This type of injury is met with in the small intestine but I think it is rather commoner in the large The cæcum with the ileum and the descending and iliac colons have all been found in this state. Interference of the blood supply also leads apparently to an ulceration of the mucous membrane which comes on fairly quickly after receipt of the wound. Captain Dunn has collected several cases of this type of injury which he will publish in due course

Escape of contents —The large intestine is often laden but the condition of the contents renders massive escape less frequent than it would otherwise be, but take it all in all the escape from the large intestine is more frequent than that from the small especially when the cæcum and ascending colon are involved

Nature of the lesions —*Cæcum* —There have been a fair number of cæcal wounds, most of them have been small in extent and have lent themselves to suture In other cases the wounds have been so long as to necessitate an artificial anus In one case there was bruising of a transposed cæcum In a good many cases there was a large retroperitoneal [illegible] It may be here recalled that this injury was in one instance accompanied by acute dilatation of stomach

Transverse colon —All kinds of wounds are met with here, from a simple single lesion to complete division True antero-posterior wounds are not very common, and as a rule the transverse colon is struck obliquely, the bullet passing through the anterior part of the lumen. It has already been stated that such wounds are accompanied by lesions of the stomach and small intestine

The posterior surface is sometimes wounded and this may be overlooked unless it is borne in mind that such an injury is possible, for it is not obvious unless a special search is made Bleeding from the vessels supplying the bowel is fairly frequent

Vertical colons—i e , the ascending and descending colon — It is convenient to take these two portions together, as they have no mesentery Both especially the descending lie rather further from the lateral line than would appear The wound may be completely intra- or extra peritoneal, or both combined The actual lesions are perforations, slits, tears or complete divisions Perforations are most commonly met with in side-to-side wounds and complete division in antero-posterior wounds All varieties are complicated with small gut injuries Makins noticed that ascending colon wounds were more common at the base than other colon wounds, and he attributed the rarity of the descending colon wound compared with that of the ascending to the former being more often accompanied by small gut injuries owing to the fact that the small gut overlies it This partially explains the discrepancy but the ascending colon is actually wounded more often than the descending The possible explanation may be that the descending colon lies so far back that any bullet passing transversely and involving it and the small intestine would traverse a transverse plane situated so far back in the body as to involve the spine and great vessels Of course an antero-posterior wound would involve both the small and large intestine here but these are not so common as the side wounds The anterior wounds of the vertical colons are comparatively easy to find and to deal with if a suitable incision is used The extraperitoneal are very difficult, and most probably are more often missed than any other They may be small and valvular and escape notice because they lie in a mass of areolar tissue, and this difficulty is very greatly increased when this tissue is infiltrated with blood as it so often is The great danger is an infection of the areolar tissue, and to this class of infection Fraser has given the apt term "colon septicæmia." I have seen it prove fatal within 12 hours and that with an open wound

Hepatic flexure —Next to the transverse colon the hepatic flexure is the easiest of all to deal with as it lies fairly superficially Its form leads to multiple injuries

Splenic flexure —This, from its position is the hardest of all the large intestines to deal with and even with the best placed incision it is difficult properly to examine without mobilisation

Pelvic colon —This portion of the large intestine is anatomically more like the small intestine than any other part of the colon and the lesions are somewhat similar There are slits perforations or complete division and these are often complicated with multiple small gut and bladder injuries Fracture of the pelvis so often associated, increases the gravity of the case. I have been struck with the great variations in position as shown by the different situations of the wounds of the gut in different cases in which the bullet has taken a similar direction The infectivity of its contents is very great, and an insignificant wound even if got early, has proved fatal

Symptoms —The symptoms of intraperitoneal wounds are similar to those of the small intestine A great difference lies in the behaviour of the extraperitoneal wounds, all grades of infection are met with Sometimes we have cases of acute sepsis with or without gas formation which are fatal in a few hours such cases are often past help when they arrive. They are cold blanched and clammy, and the pulse running—in fact their appearance often suggests acute hæmorrhage The dangerous sepsis shown by high mortality accompanying artificial ani when formed in the vertical colons has led some operators to always make an attempt [illegible] close the wound Unfortunately the damage is often alr[illegible] done when the case has come under treatment. In other cases especially in antero posterior wounds or cases with a single wound in the loin the symptoms are less acute Some such cases arriving late and left may do well at first, then the usual signs of intoxication and local tenderness appear In such cases an incision opening up the wound causes an amelioration , a certain number of such cases appear not to be cases of colon infection but due to infected material carried in with the projectile

---

[1] Lectures I and II were [illegible] in THE LANCET April [illegible] and [illegible] [illegible]

Prognosis —Figures seem to show that there is no great difference between the small gut and the large gut in the operated series of cases, though one must remember that in unoperated cases the small intestine is much more fatal, and one can say that small gut injuries are largely fatal from hæmorrhage and shock, while the great gut injuries are fatal from sepsis, especially retroperitoneal sepsis This difference, of course, is due to the greater toxicity in the large intestine, which is known to all It is possible that operative treatment may cause the death in a certain number of colon wounds which might have got well under the old conditions, but with the increased use of a transverse incision for the exploration of such wounds the dangers ought to be greatly reduced

It is interesting to compare two series of figures In 310 cases of penetrating wounds of the abdomen under operative treatment at the front the small gut mortality was 63 8, that of the great gut 60

Makins's figures, which refer to cases at the base in the pre operative days, show the mortality to have been as follows Large gut mortality 38 7, small gut mortality 86 per cent One must remember here, of course, that there was a great elimination of both classes of case

Very few cases, apparently, of transverse colon wounds used formerly to reach the base, and this was attributed to its position favouring the spread of sepsis, but I am inclined to think that it was not so much this as to its frequent association with small gut injuries The reason for the vertical colon cases reaching the base seems to have been an anatomical one, for those colons are tucked away at the side of the body and their situation is very favourable for sealing off a local infective area

I have not been able to trace, so far, any great disparity as regards danger in the different portions of the large intestine

Treatment —In spite of the fact that some colon cases did arrive at the base and recover, I do not think that there are any surgeons who have had experience at operating who would advise abstention on this ground except in cases which arrive late

Incision —It may still be necessary to use a paramedian incision for a general exploration of the abdomen for the exclusion of, or for dealing with, other injuries The transverse and pelvic colons are best dealt with from such an incision, as these lesions are commonly associated with those of the small gut It may be necessary in certain cases to supplement this median incision with one towards the side of the body When the projectile has traversed only one side of the body the horizontal loin incision is by far the best, and here again the value of an X ray examination in cases of single entry wounds is to be insisted on. The rectus sheath may be preferred by some for exploration of the hepatic and splenic flexures, but the association of kidney injuries with these wounds makes a horizontal incision more desirable, as the kidney can be dealt with in the posterior extremity of the wound, whereas an attempt to remove the kidney through the anterior incision is not very convenient or desirable Open wounds involving the loin, and possibly involving the colons, can be dealt with by local enlargement, but in the absence of X rays a median incision to exclude other injuries is most probably desirable

- *The local lesion* —The question of treatment is determined by the nature of the lesion Suture should be attempted whenever possible, but a colostomy is often necessary to save time when other lesions have already been dealt with If suture is employed in the uncovered parts of the colon adequate drainage must be established.

Proximal colostomy —I thought when starting work that proximal colostomies would have a much wider application than I have found to be the case They are, of course, useful in limiting the amount of septic absorption in cases of large wounds of the vertical colons, but, as has been pointed out, this tissue is already infected at the time the case has come under treatment , and, in addition, one does not feel inclined to make an extra opening in the bowel and proximal colostomy to be of any use must be complete and must probably find its best application in these cases of loin wounds on the left side in which sepsis develops late, and in some wounds of the rectum A cæcostomy is a perfectly useless procedure

Rectal Wounds

These may be either extra or intra peritoneal or both.

(*a*) The extraperitoneal ones are often accompanied by wounds of the buttock and fractures of the sacrum The latter are especially dangerous, as sepsis spreads rapidly in the retro-rectal areolar tissue The treatment is a free external opening and possibly a proximal colostomy

(*b*) Intraperitoneal wounds are best treated by suture In those cases where this is impossible it may be worth while closing the bottom of Douglas's pouch above the lesion and introduce a tube through the anus into the space thus shut off The question of a proximal colostomy must also be considered

Liver

Frequency —Out of 965 cases the liver was wounded 163 times Liver wounds furnish a large proportion of the cases in which no operation was performed

Organs wounded with it —The stomach, colon, small intestine, and right kidney are those usually wounded with the liver The pleuræ are often involved The liver is often found wounded in cases of an exploratory cœliotomy where the entrance wound is far away Many cases where the liver is obviously wounded are only submitted to operation to exclude the wounds of other organs

Nature of injuries —A good-many cases of rupture by horse kicks have been seen, but most of the wounds are caused by projectiles or by ribs driven in by the missile Makins says that transverse wounds were the most common at the base The wounds are of all types a simple perforation, an avulsion of fragments especially of the anterior edge, to an almost complete disruption

The wounds are usually commensurate to the size of the projectile thus bullets, small shell and bomb fragments make perforations or scores , larger shell fragments more ragged wounds Its friable nature, as would be supposed, lends itself to tearing and fragmentation , thus there may be radiating fissures from a central hole crater like exits or pieces nearly or completely torn off In some cases a bullet produces extensive destruction These are said to be caused by short-range wounds, but of this I am not convinced The track or torn surface is at first ragged and bloody , seen after 12 or 24 hours it becomes a dirty yellow brown, and later it may be a vivid yellow colour due to bilious staining The injury, to judge from the microscopic sections, is usually limited to the vicinity of the wound, and in those cases where destruction of cells is found at some distance from the wound it is most probably due to an infarction phenomenon Anyhow these infarcted areas are by no means uncommon

Hæmorrhage varies , it is not altogether commensurate to the size of the injury and its amount largely depends on whether a big vein has been opened or not—if not bleeding usually ceases spontaneously in from six to ten hours The gall bladder, common and cystic ducts have all been wounded, but the larger bile passages do not seem to be so often wounded as one might expect Sometimes in the abdomino-thoracic wounds the bile escapes into the pleura.

Symptoms —The symptoms are often slight and one has no doubt in deciding that the right course is the "expectant" one Sometimes the symptoms seem surprisingly severe and I can recall two cases of tangential wounds of the liver which could not have involved the liver deeply and in which there was no sign of blood in the abdomen Both cases were extremely shocked and one ended fatally, unfortunately there was no post-mortem There are the usual signs of abdominal injury, the main ones being those of hæmorrhage which manifested itself in the usual way

Jaundice —Jaundice of a slight and evanescent character, accompanied by bile in the urine in some cases, is seen in the early stages , it is of no great importance and usually passes off , its cause is not known The septic form of jaundice which is seen at the base in a considerable number of cases, and which not infrequently ends fatally, is also seen at the front within three or four days of the receipt of the wound There has also been one case of severe biliary peritonitis which ended fatally 36 hours after receipt of the wound There was much bile in the peritoneum, and no other injury to account for the peritonitis. Of course it is impossible to deny that infection may have been carried in with the projectile I quote this case because there is considerable difference of opinion as to whether bile can cause peritonitis In the pleura, apparently, it is often quite innocuous

For the late facts of liver wounds I cannot do better than refer you to Sir George Makins's paper on this subject which appeared in the *British Journal of Surgery* (No. 12, iii., 1916).

Prognosis.—This may be said to be good. Thus we have 114 cases and 38 deaths. Shock and hæmorrhage are the common causes of death. In uninfected wounds mortality has a distinct relation to the amount of injury, both on account of the amount of blood lost and of the amount of injured substance. No connexion has been traced between the direction of the projectile and the fatality. Injuries of the big bile passages do not seem to increase the gravity to any appreciable extent. Attention has already been drawn to the grave symptoms of apparently trivial injuries.

Treatment.—Many cases require no operation, as there are obviously no other organs wounded. Many cases are operated on because of the possibility of injury to other organs and the bleeding in the liver wound found to have ceased.

The incision for an obvious liver wound is either an "f" shaped rectus incision or a sub-costal. A French surgery recently brought out recommends an incision parallel to the costal margin which passes through the costal cartilages. Access to the dome of the liver is said to be greatly facilitated by this method. The actual treatment of the wound when found consists in leaving it alone, packing it, or suturing. The latter is not very satisfactory. The big bile-passages can be dealt with on ordinary lines by suture and drainage.

Pancreas.

Frequency.—Very few of such injuries come under review—so few as to suggest that most of them are rapidly fatal. The association of the gland with the big vessels need hardly be mentioned.

Symptoms.—There are no distinctive symptoms, the lesion being found at explorations and accompanied by fat necrosis. The wasting so often seen in civil injuries and the formation of Jordan Lloyd's cysts have not been seen.

Prognosis.—One case was sent to the base in which the pancreas was obviously perforated by a bullet, the other cases were fatal. Makins has published some cases of wounds of this organ which he had seen at the base. He says that they were discovered during the performance of operations for intestinal injuries and that the typical results of the escape of the pancreatic juice have been observed. They have usually proved fatal. He mentions one interesting case in which an abscess formed and opened, in which the patient eventually recovered and was discharged to England. This man walked six miles after receiving his wound and suffered no abdominal pain. He had been retained some time at the casualty clearing station on the suspicion of an injury to the alimentary canal.

Spleen.

Frequency.—Wounded 54 times in 955 abdominal operations.

Associated injuries.—The kidney is most frequently injured with this organ, the splenic flexure is fairly frequently associated with it. The curious absence of combined stomach and spleen wounds has already been noticed. The thorax is often involved, though usually only at its inferior limit.

Nature of injuries.—These consist of perforations, tears, slits, avulsion of the upper and lower poles, and complete disruption. It is often injured by broken ribs, and rupture through an intact diaphragm has been described, the wound being produced in one case by a piece of hard clay.

Symptoms.—These are mainly those of hæmorrhage, and the diagnosis is made on these and on the position of the wound. Very often it is only found wounded in the course of an exploratory operation. There is nothing special about the hæmorrhage, and the damming up of blood in the left loin which has been said to be a feature of this injury in civil practice has not been conspicuous in the present campaign. The amount of hæmorrhage varies very much and depends mainly upon whether the vessels are injured. Unless this is the case the hæmorrhage has usually ceased when the abdomen is opened.

Prognosis.—This is good unless the other organs are involved or the main vessels of the organ torn. Experience at the base obtained by post-mortems on cases fatal from other reasons has shown the healing of many spleen injuries. The loss of the organ does not seem to cause any great shock. There must be many cases of soldiers in the army without their spleen who offer a good opportunity for examining the result on the blood produced by loss of this organ. I should be much obliged if any of those who come across such cases could let me have the result of the blood examination.

Treatment.—In uncomplicated wounds a subcostal or a rectus sheath incision with a transverse extension is most suitable. The kidney is very likely to be wounded, and has been removed in several cases with the spleen. If the hæmorrhage has ceased, the organ is best left alone; the suturing or packing will control the hæmorrhage if this is going on. As a matter of fact, sutured holes are apt to bleed almost as much as a raw surface unless the hæmorrhage is fairly free. Excision should only be resorted to if the organ is totally disrupted or the vessels torn.

One point has to be borne in mind in operating on those cases, especially if associated with wounds of the kidney vessels. The hæmorrhage, which very likely has been controlled or diminished by the clotting, is likely to restart in an alarming manner directly the clot is disturbed. It is therefore absolutely necessary to have everything ready for the arrest of the hæmorrhage.

Mortality and causes of death.—Shock and hæmorrhage are the main causes of death. One curious case may be quoted, that of a simple perforation of the spleen that died suddenly without cause on the fifth day.

Kidney.

Frequency.—The kidney was wounded 73 times out of 965 peritoneal operations. I have seen two cases in which both kidneys were injured, both were fatal.

Associated organs.—The spleen, liver, and colon are the organs most frequently associated, and, curiously enough, the spleen and right kidney have been wounded without other injury than perforation of the vertebra, which in this case was unaccompanied by paraplegia. The case was fatal from a late recurring hæmorrhage in the spleen. The right kidney is commonly associated with injuries of the liver and hepatic flexure and the left with injuries of the splenic flexure and spleen.

Nature of lesions.—The nature of the projectile has no particular effect on the injury, and, as is the case with other solid organs, the kidney is liable to extensive rupture. The actual lesions may be perforations, scores, furrows, avulsion of poles, and hemisection; sometimes the kidney is found lying loose, the pedicle having been ruptured. Sometimes the pelvis is alone perforated; sometimes the vessels are completely divided, the ureter remaining intact. The amount of hæmorrhage depends largely upon whether a vessel has been injured or not; there is very often considerable perinephric hæmatoma. In contra-distinction to civil injuries intraperitoneal hæmorrhage is very frequent.

Symptoms.—The shock is not, as a rule, very great and depends largely on the amount of blood lost, and this perhaps is peculiar when one remembers the effect produced by the kidney blow in boxing. The dullness due to free fluid in the abdomen is more common than in civil injuries and manifests itself in the right or left side according to the organ injured. *Hæmaturia* is usually present, but it may not occur at once. The absence of this sign is due either to suppression, to the presence of clots, or to pieces of kidney in the ureter. Profuse hæmorrhage into the bladder is not common in the early stages. Hæmaturia usually clears up in a few days, but may persist. *Extravasation of urine* is not marked unless the pelvis has alone been injured.

Secondary complications.—A secondary hæmorrhage is a fairly frequent late complication and occurs apparently most frequently during the second and third week after injury. The urine is generally contaminated. Sometimes the secondary hæmorrhage starts afresh, or it may manifest itself as an exacerbation of a persistent primary hæmorrhage. Unlike primary hæmorrhage, it is often accompanied with clotting of the blood in the bladder. Gas infection of an effusion of blood round the organ has been met with.

Treatment.—Many cases require no operative treatment. Sometimes it is advisable to open up the loin wound. Many cases of kidney injury are found after an exploratory cœliotomy complicating other visceral injuries. If the kidney is found to be not much damaged all that is necessary is a puncture drained into the loin; if much damaged nephrectomy may be necessary.

As was stated in talking of splenic injuries, the hæmorrhage from wounded kidney vessels is very liable to restart with alarming rapidity directly the clots are disturbed, and it is rather interesting here to mention that the number of kidney wounds treated seems to be larger at an advanced operating centre than in the casualty clearing station This is most probably due to the fact that the cases arriving earlier have not suffered so much from hæmorrhage The treatment of secondary hæmorrhage is ablation of the organ, care being taken at the same time that the bladder is empty of clots

Mortality and causes of death —Shock and hæmorrhage are by far the most common at the front

Ureter

This is not very frequently injured, and the cases that we have had have done well There are no particular symptoms and the injuries are found during explorations Treatment follows civil lines

Bladder

My own opinion has undergone a change, and I now think that these injuries are more dangerous than I did after a few months experience at the front, and I believe that the danger is an inherent one and apart from the complications to other injured organs The bladder was wounded 45 times in 965 operated cases In 25 cases it was the only organ injured

Associated injuries —The small intestine and fractured pelvis

Nature of injuries —They may be either intra or extra peritoneal or both The intraperitoneal lesions—perforations, tears, or slits—are *very often not extensive* The extraperitoneal wounds, often accompanied by much hæmatoma, are slits or tears They are usually situated at the sides of the bladder and may be often caused by bony spicules The intra and extra peritoneal are usually caused by oblique wounds entering by the lower lateral part of the bladder and passing out through the peritoneal surface Projectiles sometimes lodge within the bladder and cause pain at a later period

Treatment —Intraperitoneal wounds are, as a rule, easily sutured, except those which occur at the very bottom of Douglas s pouch The bladder should be explored for a foreign body A suprapubic drainage is not here necessary Catheterisation for a few days may be necessary or a catheter may be tied in, although this treatment is not to be continued for long

Extraperitoneal wounds —These are treated by an incision down to the wound in the bladder, which latter may be sutured, if possible and a drain left in the space formed by the operation If the wound in the bladder cannot be sutured it is most probable that a drain down to the wound will be sufficient , if there is any doubt a tube placed in the organ is *most probably the safest course*

Colonel A Fullerton, who has had much experience of these cases at the base, does not think that a suprapubic cystostomy is necessary in extraperitoneal wounds, as he has often seen cases at the bases do well discharging urine through the various fistula tracks caused by the projectile's entrance through the buttocks or upper thigh He states, and justly, that urine is an aseptic fluid, and therefore need not be feared It is quite true that many such wounds may reach the base, but at the front one sees cases wounded extraperitoneally do badly and show signs of septic intoxication , and when one has seen such cases do badly one does not feel inclined to hold one's hand

Mortality and causes of death —Uncomplicated cases have a mortality of 56 per cent The causes of death are shock and hæmorrhage associated with fractured pelvis and, a few days later, sepsis

Protrusion of Omentum and Viscera

By this is meant, not the exposure of the abdominal contents through a large gap in the abdominal wall, but their prolapse through a wound very often comparatively small

The omentum —As would be expected, the omentum is most frequently seen in this connexion It appears in larger or smaller amounts in wounds situated all over the abdomen and also in those situated in both hypochondriac regions, where it reaches the outside of the body through the interspaces or through broken ribs where one hardly would expect to see it appear The method of extrusion is twofold it is either (1) carried out by the projectile, or (2) is driven out by the intra abdominal pressure either through the entrance or exit wounds

In one case where a shell fragment had entered above the umbilicus in the mid line and had come out in the right loin behind the lateral line of the body, the omentum was so firmly carried into the long oblique exit wound that it required considerable force to release it , it was, in fact, strangulated within the abdominal wall, though none of it showed externally

Before operation became the rule it was usual to leave these tags to slough off and probably this is still the best course to pursue if the cases are seen late If seen early it is best to treat such cases as other abdominal wounds and explore In several instances in which this had been done the intestine has been found wounded

The stomach —This has been found herniated by itself or in association with the spleen, splenic flexure, and small intestine In one case it was successfully sutured and replaced, though too much of the abdominal wall had been carried away to allow the external openings to be closed.

Liver —This organ has also been partly herniated

Small intestine —Next to the omentum the small gut is most frequently herniated , and here again, as in the case of the omentum, it may be carried out or expelled. Sometimes a knuckle lying outside has been actually wounded, in other cases the extruded knuckle has been intact, but there have been numerous lesions within the abdomen

If seen early the ordinary rules apply, and the abdomen should be opened and the lesions repaired , if seen later—over 24 hours—it is not probable that anything can be done, but still it is better perhaps to explore if the condition of the patient justifies it

Colon —The transverse colon has been herniated In one case the gut was tightly herniated in the wound and, as the injury was two days old the constriction was relieved and an artificial anus established

---

ANÆSTHETICS FOR MEN WITH WOUNDS OF THE ABDOMEN,

BY CAPTAIN GEOFFREY MARSHALL R A M C

A patient with a penetrating wound of the abdomen usually shows signs of shock In a typical case the face is pale the extremities cold, the pulse rapid and the blood pressure below normal If put to bed and surrounded with hot bottles the man s general condition will improve Both surface temperature and blood pressure rise It is important *that heat-loss should be prevented during the course of* operation

The choice of anæsthetic —Men who have been wounded less than 40 hours previously are not good subjects for spinal anæsthesia Intrathecal injection of stovaine is *followed by a great* fall of blood pressure, which may be fatal. Men with wounds of the abdomen appear to be no exception to this rule. The writer's experience of spinal anæsthesia for these cases has been limited and unfortunate Three patients were each given 0 07 gm stovaine They all died within a few hours of operation Chloroform is an unsuitable anæsthetic The blood pressure falls steadily during the course of the administration If the operation is prolonged the patient may die before the abdomen is closed or during the next few hours

Ether remains the drug most generally used Good results *have been obtained with open ether Its* chief disadvantages are 1 The loss of body heat caused by the prolonged inhalation of cold vapour This is especially noticeable in the theatres of clearing stations which are commonly lodged in tents or temporary buildings *difficult to keep really* hot 2. Irritation of the respiratory tract This is most serious in winter, when many of the wounded have some bronchitis before operation Men wounded in the abdomen are particularly liable to develop bronchitis This may be due to deficient movement of the lower chest At this clearing station the proportion of cases which had bronchitis after operation was 54 per cent when open ether was used With warm ether vapour the percentage dropped to 14 7 These figures were obtained from two comparable series of cases occurring in the same months of two successive years

Ether should not be given by the intravenous method to men suffering from shock In these cases profound collapse may occur within two hours of administration

In our experience the most satisfactory way of administering *ether or chloroform* is by the Shipway apparatus[2] The patient inhales a warmed mixture of air and anæsthetic vapour Induction is quiet and rapid The absence of struggling may save much bleeding from wounded vessels Breathing is easy and noiseless There is a remarkable absence of secretion The patient recovers consciousness quickly and vomiting is rare. It is usually possible to give fluids by mouth within two hours of operation. In lengthy operations it is an advantage to pass oxygen instead of air through the ether

---

[2] THE LANCET 1916, i 70

When the projectile has penetrated the chest as well as the abdomen ether should not be used It is apt to provoke fatal intrathoracic hæmorrhage In these cases we have found the most successful sequence to be a preliminary injection of hyoscine 1/100 gr, morphia 1/6 gr, and atropine 1/100 gr This is followed by a minimal amount of warm chloroform vapour and oxygen.

It is not necessary to give atropine before a warm ether vapour anæsthetic. We have not found any advantage in doing so In the majority of cases morphia should be withheld before operation, or given only in small doses A man recently injured is particularly susceptible to further shock. This susceptibility is greatly increased by large doses of morphia.

Factors causing fall of blood pressure during abdominal operations—During the course of an ether anæsthetic the blood pressure shows a tendency to rise If there is much manipulation of gut and peritoneum it will fall gradually The process however, may be continued for hours without the blood pressure falling to dangerous levels Exposure of gut outside the abdominal cavity produces a much more serious effect If more than two or three feet of gut are exposed the blood pressure will commence to fall after a few minutes It will continue falling rapidly until the gut is replaced This effect is seen when great omentum only is exposed Surgeons should be urged to make big incisions, and work as much as possible with the gut lying inside the peritoneal cavity

Apart from copious hæmorrhage, there is one other procedure which causes rapid fall of blood pressure. This is turning the patient on his side The effect is only produced if the patient has been under the anæsthetic for a considerable time before being turned At the end of an abdominal operation the patient may be in good condition He is then turned on the right or left side so that the surgeon may excise a wound in the back. In a few minutes there is a great fall of blood pressure and the radial pulse disappears It may be hours before the patient recovers this lost ground

The indication is that wounds of the back should be dealt with before laparotomy Turning the patient has no ill effect in the first half hour of an ether anæsthesia.

CAUSES OF FAILURE.

It has been sufficiently indicated that the chief causes of failure are hæmorrhage shock, and sepsis Hæmorrhage and shock are the early causes sepsis are later The latter is of two kinds (*a*) Peritonitis as the result of soiling the peritoneum with intestinal contents or that carried in by the missile, (*b*) the sepsis which occurs in colon wounds on the uncovered portion of the bowel. To these causes must be added two more

Mental and physical strain—It is commonly said that the surgeon in war has the advantage over his peace colleagues in that his subjects are healthy young adults This of course is true but still there is the strain caused by days of watching and alertness and of nights when sleep is difficult, interrupted or impossible to obtain Just before an action very likely both artillery and trench mortar bombardment increase to their maximum Then there is the exertion of battle coming on the top of days of constant strain The excitement of battle for the time being at any rate obliterates all sense of fatigue so that many men do not know how tired they are until some wound is received which prevents them going farther Then there is the journey which we have already described to the casualty clearing station Sometimes the men arrive practically asleep and resent any interference or examination Other men arrive in whom a state of excitement is still present and they are wakeful and anxious to chatter about their experiences Then after being fed they are dressed and if they do not fall asleep in the process they do so immediately afterwards, and it is one of the most striking sides of the medical side of war to see a large room filled with men lying on stretchers—some slightly wounded some severely, some mortally but all asleep and asking for nothing but sleep It [illegible] body and soul It is on such patients that the surgeon has to work and it may well be imagined how much the mental and physical strain increases the shock of the injury

Complicating injuries—One need say very little on this subject except that every kind of bodily injury may be added to that of the abdomen. Compound depressed fracture of skull fractured long bones, multiple wounds, fractured spine, and avulsed limbs are among such complicating injuries and when one considers the total mortality and in appraising the worth of abdominal surgery one must take these injuries into account, it may be said that were it not for such extraneous injuries the mortality would be considerably lower No attempt has been made in the operative table to show such injuries

THE FUTURE.

It cannot be denied that the measure of success that has been obtained in abdominal surgery and for the matter of that in other wounds is principally due to the fixity of the battle-line Can the high standard be kept up if the armies get on the move? The answer is doubtful It largely depends on whether it will prove possible to render the casualty clearing station sufficiently mobile to prevent a large gap recurring between it and the field ambulance We shall never be in the same condition as we were in Africa, as the motor ambulances have largely minimised distance, but the motors will never be able so to eliminate space as to make a casualty clearing station far back as useful as one well up

The two most importance functions of a clearing station are (1) To warm and feed men, (2) to operate upon them under reasonably favourable conditions The cook house and the theatre supply these conditions Nursing and after-care are important but it is better to operate on an abdomen and let a man lie on a stretcher than not to operate on him because beds and nurses are absent

Shall we return to the expectant treatment if the war changes its character? I am inclined to think not People have learnt that the abdomen is not such a fearful place and that good results can be obtained without the elaborate surroundings that were formerly thought necessary The peritoneum has ceased to be the bogey that it was

RESULTS

The table published with this lecture tells what has been accomplished I would only add that every attempt has made to find out what could be done by surgery for the abdominally wounded. The mortality has been reduced at the front by some 10 per cent., and many fewer cases now die at the base The period covered by these figures extends over 18 months so that a fair average has been struck. The 18 months were mostly what is euphemistically called a quiet time, but included one period of strenuous fighting It is interesting to note that the mortality over a period of 18 months is the same as that for the first six months of that time, which fact seems to show that the figures represent a true picture of what may be expected from operative treatment

The main results may be summarised as follows —

Total number of cases	1200	No operation considered advisable	73
Arrived moribund ..	250	Total operations ...	965
Total mortality excluding moribund	50%	Total operative mortality	54%
Total mortality including moribund	60%	Total hollow viscera mortality	65%
Considered with view to operation	1032	*Stomach mortality	53%
		*Small gut mortality	66%
		*Great gut mortality ..	59%

* Uncomplicated by wound of any other hollow alimentary viscus

Table of Operations

Operation.	To base.	Died	Operation.	To base.	Died
Suture of stomach ..	25	29	Proximal colostomy	4	10
Suture of stomach and other operations on intestinal tract	6	21	Cœliotomy no hollow viscus perforated ...	89	33
Resection of small gut	25	83	Cœliotomy liver wounded	76	38
Resection of small gut and other operation on intestinal trac	5	3	Kidney exploration of	25	7
Suture of small gut	49	71	Kidney excision of	6	7
Suture of small gut and other operation on intestinal tract ...	17	33	For wounded bladder	11	14
Small gut anas ...	—	7	Spleen exploration of	12	4
For small gut fistula	2	1	Spleen excision of ...	4	12
Suture of great gut ...	50	52	Miscellaneous	10	21
Great gut anas	13	35	No operation advised	69	4
For wounded rectum	3	5	No operation moribund	—	250
			Grand total	513	775

NOTE.—In the case of injury to hollow viscera there were wounds of the solid viscera which are not shown. Thus in the case of suture of stomach of 29 fatal cases 11 were complicated by wounds of the solid viscera

ABDOMINAL SURGERY AT AN "ADVANCED OPERATING CENTRE"

By GERALD S HUGHES, M B Lond , F R C S Eng ,
CAPTAIN R A M C (T F) SURGEON YORK COUNTY HOSPITAL;
AND
W A REES, M D Lond , F R C S Eng ,
CAPTAIN R A M C (T C)

Out of the 640 cases of severe injuries to the abdomen head, or chest, received at this advanced operating station in six months 263 of them were wounds of the abdomen Several records of abdominal work at the front have been published, but so important is this branch of surgery, and so different in many respects from abdominal work at home, that it is important that the experiences of those doing this work should be recorded

The hospital is stationed close up to the line and is thoroughly equipped for dealing with urgent surgical work The wounded are nursed by sisters with a staff of orderlies, and the permanent officers are a surgical specialist, an assistant, and an anæsthetist, constituting "a team" The time elapsing between the receiving of the wound and the admission to hospital depends on the time taken in getting the patient back to the advanced dressing station, from which he is sent direct to us It is generally longer during an attack than in times of quiet

As soon as the patients arrive they are taken to a receiving ward and placed in beds always kept ready warmed, where they are examined, the findings noted down, and the position of the wounds marked on diagram These notes are subsequently transcribed into the Special Abdominal Book issued by the Committee of the Medical History of the War, and have added to them later the notes received from the base and from the home hospitals Thus a complete history of the case is kept from the receipt of the wound until the time the man is finally discharged

The patients remain in the receiving ward until they are taken to the theatre for operation, or, in those cases where an operation is definitely contra indicated, to the wards It is an important point in a hospital at the front not to send abdominal cases into the general ward for observation, as if this is done in a rush there is a danger of these cases being overlooked, and for the same reason patients in a seemingly moribund condition are not removed from the receiving ward, so that if their condition at any time improves they can immediately be sent to the theatre

Question as to whether the Wound is Penetrating

In dealing with abdominal cases the first question to be decided is whether the wound is penetrating or non-penetrating—that is to say, whether the missile has entered the peritoneal cavity causing visceral injury, or whether it is a "contour wound" involving only the abdominal wall To help one to decide this question and in examining every patient with an abdominal wound the following points must be considered —

1 *Facies* This sign does not possess the same value as it does in abdominal conditions met with in civil practice Most of the men brought in with severe wounds wear an anxious and worried mien

2 *Pain* This is always present in wounds of the gut It is also present in retroperitoneal hæmorrhage with its consequent stripping off of the peritoneum from the tissues, it is especially severe when it takes place on the posterior surface of the abdomen, of course, pain is very much modified by the amount of morphia that has been given

3 *The pulse* is small in volume but varies greatly in frequency and may be comparatively slow In the series of 110 cases on which laparotomy was performed it was under 100 in 64 Any irregularity of the pulse is a bad sign

It is very noticeable at the front how small, owing to the contraction of the arteries, the pulse may be in limbs which have been exposed to the cold One patient who was admitted with a mere superficial wound had an almost imperceptible pulse at the wrist, whereas the pulse in more protected parts of the body (e g , dorsalis pedis) was quite good in both volume and tension The arms had been exposed outside the blanket on a cold day during the journey to the hospital

4 *Vomiting*, if present, is a sign of peritoneal irritation In cases of stomach wounds it nearly always occurs, with or without hæmorrhage Its importance is modified by the fact that a large number of those who are wounded in other parts of the body are liable to be sick

5 *Abdominal rigidity* is widespread and continuous in cases of injury to the hollow viscera It is not so marked in cases of excessive hæmorrhage and it tends to pass off in the last stages just preceding death Abdominal rigidity also occurs in wounds of the lower chest, but in these cases, if the hand is laid on the abdominal wall, the muscles will be found occasionally to relax and an incomplete respiration taken More localised rigidity is produced by a contour wound or hæmorrhage associated with it Rigidity that is due to a chest wound is found to relax if the patient's shoulders be well raised and a pillow be placed under the knees

6 *Tenderness* is perhaps the most important sign of penetration of the abdominal cavity with injury to the gut It is not usually limited to the area of the wounded gut, but is more generalised It is not so marked in cases of injury to the solid viscera

7 *Hæmorrhage* —In most penetrating wounds one gets some internal hæmorrhage, which shows itself by dullness in the flanks and hypochondrium In very rare cases hæmorrhage may be present in the peritoneal cavity without any breach of the peritoneal surface

8 *Liver dullness* —The presence or absence of liver dullness cannot be relied on It has often been noticed to be absent in cases where there has been no injury to gut, and free air in the peritoneal cavity is scarcely ever met with even in wounds of the stomach At an operation the stomach may be seen distended with gas which has not escaped though there is a penetrating wound in its wall It is interesting to note that liver dullness is often absent in moribund cases Out of a series of nine such cases seen in sequence the liver dullness was absent in seven The explanation of this probably is (*a*) that shrinkage of the liver has occurred from excessive bleeding A small contracted liver is almost invariably met with in operating on cases where there has been much bleeding into the peritoneum (*b*) That there is a paralytic distension of the gut

9 *Position of wound of entry* —It should be noted that nearly all of our cases were examples of wounds by bombs and shells, many of which necessarily burst upon the ground and just as frequently behind or beside the patient as in front of him This is probably the explanation of the fact that a considerable majority of our patients were wounded behind a line drawn from the anterior fold of the axilla to the anterior superior iliac spine In no less than 23 out of the series of laparotomies and also in several of those who were admitted in a moribund condition the missile had penetrated through the buttock, and therefore when wounds are received in this region the possibility of the foreign body having entered the abdomen must never be overlooked In wounds of the back, with damage of the structures lying beneath the peritoneum, symptoms are often produced which simulate those found in penetration of the abdomen This is exemplified by the following case —

Private B was admitted on Nov 13th with a wound to the outer side of the left erector spinæ muscle and the second lumbar vertebræ On examination of his belly it was found that he had dullness, pain and tenderness on the left side of the abdomen He was rigid, but the rigidity was confined to the left half, and it was mainly this latter fact which made us conclude there was no penetration of the abdominal cavity, but that it was a case of retroperitoneal hæmorrhage

A second case exemplifying the same association of symptoms was the following —

Private H admitted Oct 16th, 1916, complained of great pain in the right half of the abdomen, he was very tender in this region, and had some dullness over the lower abdomen The wound of entrance was on the inner side of the left gluteal fold and these signs and symptoms were produced by the missile having passed upwards and forwards into the right abdominal wall and having caused a large extra-peritoneal hæmorrhage with bleeding from the deep epigastric artery In this case so closely did the signs and symptoms simulate those of a penetrated gut that exploratory laparotomy was performed Enough importance had not been attached to the fact that the rigidity was confined to the right side of the abdomen It has been pointed out above that the rigidity is almost always general in wounds of the gut

When the wound is received higher up, at or near the costal margin, the case may be complicated by damage to the pleural cavity or liver These cases will be considered at a later period

The size of the wound of entry may be some indication of the damage received internally, and a useful working rule is this A large wound with few abdominal symptoms suggests the probability of little or no damage internally, whereas a small wound with well defined abdominal symptoms is a clear indication of a lesion of the abdominal contents In doubtful cases exploration under an anæsthetic may be

7 *Hæmorrhage*—In most penetrating wounds one gets some internal hæmorrhage, which shows itself by dullness in the flanks and hypochondrium In very rare cases hæmorrhage may be present in the peritoneal cavity without any breach of the peritoneal surface

8 *Liver dullness*—The presence or absence of liver dullness cannot be relied on It has often been noticed to be absent in cases where there has been no injury to gut, and free air in the peritoneal cavity is scarcely ever met with even in wounds of the stomach At an operation the stomach may be seen distended with gas which has not escaped, though there is a penetrating wound in its wall It is interesting to note that liver dullness is often absent in moribund cases. Out of a series of nine such cases seen in sequence the liver dullness was absent in seven The explanation of this probably is (*a*) that shrinkage of the liver has occurred from excessive bleeding A small contracted liver is almost invariably met with in operating on cases where there has been much bleeding into the peritoneum (*b*) That there is a paralytic distension of the gut

9 *Position of wound of entry*—It should be noted that nearly all of our cases were examples of wounds by bombs and shells, many of which necessarily burst upon the ground and just as frequently behind or beside the patient as in front of him This is probably the explanation of the fact that a considerable majority of our patients were wounded behind a line drawn from the anterior fold of the axilla to the anterior superior iliac spine In no less than 23 out of the series of laparotomies and also in several of those who were admitted in a moribund condition the missile had penetrated through the buttock, and therefore when wounds are received in this region the possibility of the foreign body having entered the abdomen must never be overlooked In wounds of the back, with damage of the structures lying beneath the peritoneum, symptoms are often produced which simulate those found in penetration of the abdomen This is exemplified by the following case —

Private B was admitted on Nov 13th with a wound to the outer side of the left erector spinæ muscle and the second lumbar vertebra On examination of his belly it was found that he had dullness, pain and tenderness on the left side of the abdomen He was rigid, but the rigidity was confined to the left half, and it was mainly this latter fact which made us conclude there was no penetration of the abdominal cavity, but that it was a case of retroperitoneal hæmorrhage

A second case exemplifying the same association of symptoms was the following —

Private H admitted Oct 16th, 1916, complained of great pain in the right half of the abdomen, he was very tender in this region and had some dullness over the lower abdomen The wound of entrance was on the inner side of the left gluteal fold and these signs and symptoms were produced by the missile having passed upwards and forwards into the right abdominal wall and having caused a large extra peritoneal hæmorrhage with bleeding from the deep epigastric artery In this case so closely did the signs and symptoms simulate those of a penetrated gut that exploratory laparotomy was performed Enough importance had not been attached to the fact that the rigidity was confined to the right side of the abdomen It has been pointed out above that the rigidity is almost always general in wounds of the gut

When the wound is received higher up at or near the costal margin, the case may be complicated by damage to the pleural cavity or liver These cases will be considered at a later period

The size of the wound of entry may be some indication of the damage received internally, and a useful working rule is this A large wound with few abdominal symptoms suggests the probability of little or no damage internally, whereas a small wound with well defined abdominal symptoms is a clear indication of a lesion of the abdominal contents In doubtful cases exploration under an anæsthetic may be necessary, the direction and depth of the wounds can then be ascertained and an exploratory laparotomy incision be made. In our experience the question of penetration of the abdominal cavity was only in doubt in 1 per cent of the total cases

Choice of Cases for Operation

No hard-and fast rule can be laid down in hours as to when a case passes from the operable to the inoperable stage. When cases arrive within 24 hours of being wounded so long as they are not moribund they are all operated on. If cases arrive later than 24 hours more careful discrimination is necessary If both wounds are in the region of the flanks, and the probabilities are that the lumbar colon only is opened, they may sometimes be left, and after a few days a fæcal fistula develops and they do well. We had three such cases and these all had an exit wound, so that the course of the missile was known. If they arrive with wounds involving the abdomen, loin, or buttock, with obvious penetration, and they are not moribund, it is best to operate at once, as the fact that they have survived 24 hours shows that they may not have very serious injuries If left they will almost certainly die.

The following is an analysis of the time that elapsed between the receipt of the wound and the operation, and shows how important early operation is —

1 Cases operated on between 1 to 6 hours after wounding —43. Recovered, 27 = 62 8 per cent Died, 16 = 37 2 per cent.

Eight of the fatal cases had such severe injuries that recovery was practically hopeless and they would not have survived to reach the operating theatre had they been brought in later

2. Cases operated on between 6 to 12 hours after wounding —33 Recovered 12 = 36 3 per cent Died, 21 = 63 7 per cent.

3 Cases operated on between 12 to 16 hours after wounding—18 Recovered, 3 = 16 6 per cent Died, 15 = 83 4 per cent

4 Cases operated on over 24 hours after being wounded—11. Recovered 5 = 45 4 per cent. Died, 6 = 54 6 per cent

Recoveries at 48 36, 33½, 32 and 30 hours respectively Deaths at 60, 36, 32, 30, 29, and 28 hours.

In the fourth class bowel injury was present in every case except one at 48 hours and in this case the omentum was herniated through the skin and several coils of bowel through the muscles under the skin. It is interesting to note in this connexion that peritonitis in itself does not mean a bad prognosis as it is found that where the peritoneum shows an early and marked reaction the cases often do well.

It has sometimes been suggested that operations should be postponed in order to allow shock to pass off, and we should strongly uphold this view in all other injuries except wounds involving the hollow viscera. In these cases in our experience, the shock never does pass off. The soiling of the peritoneum must tend to keep up shock. The statement, that for the most part shock never passes off is borne out by the fact that of 36 cases admitted in an almost pulseless condition only three rallied, these were all cases where the liver only was wounded and all three recovered without operation Bowel cases always steadily deteriorate by being left Another reason for immediate operation is that internal hæmorrhage may be still taking place. These remarks are chiefly based on experience of shell wounds bullet wounds being relatively uncommon here. The only delay which is justifiable is in cold weather and if the patient had been lying out for some time In these cases it is essential that he be thoroughly warmed before his operation but this should never take more than half an hour to an hour

The next difficulty in the choice of case for operation is the decision in wounds of the solid viscera—e g liver and spleen—and the decision is rendered more difficult by the fact that in many of these cases the missile has passed through the pleural cavity before entering the abdomen The track of the missile is estimated as accurately as possible and if it is probable that the liver only is wounded no operation is performed unless there are signs of excessive internal hæmorrhage. We have notes of 11 cases of wounds of the liver treated on expectant lines, of these, 7 recovered and 4 died. Five developed pus in or around the liver and 3 succumbed to this sequela. Twenty-one cases of wounds of the liver had to be opened up and in 9 some hollow viscus was found to be wounded as well From this it is clear that the majority of wounds of the liver must have an exploratory laparotomy performed. A button hole incision is utterly useless owing to the large amount of blood in the peritoneal cavity If the splenic region is involved, laparotomy is more frequently necessary as there is more likelihood of some hollow viscus being wounded. Hæmorrhage from the spleen is not usually dangerous unless the large vessels are injured

In the series of 110 laparotomies one or other kidney was found to be wounded in 14 In every case this was in association with other injuries In none of our series of 263 abdominal cases was operation necessary for the kidney condition alone, although damage to this organ was fairly frequently met with as shown by pain and hæmaturia

The complication of the passage of the missile through the pleural cavity before entering the abdomen does not contra indicate the performance of laparotomy It was present in 18 of our series of laparotomies 10 of which recovered. In the majority the solid viscera only were wounded, but in one successful case the bowel was injured as well, another bowel case died from the effects of hæmothorax. In only one case did the operation so aggravate the chest condition as greatly to contribute towards the fatal results In these cases the anæsthetic of choice is chloroform, hypodermic injection of morphia and atropine having been previously given. It is not advisable to attempt to drain the wound of the liver through the pleural cavity, as of necessity this involves infecting the pleura In all chest cases great care is taken to drain any hæmothorax that may be present as soon as it is found to have become septic. Occasionally in suitable cases we have tried sewing up the chest wound after excising its edges in order to prevent infection of the pleural cavity

To show how capricious the course of a bullet may be, the following case is cited —

Private E was admitted 60 hours after being wounded. His wound of entry was on a level with the first lumbar spine and 7 cm to the left of it, the shrapnel ball could be felt under the skin, lying on the sixth right chondro-sternal junction His general condition was good he had slight vomiting, hæmaturia, and dullness in the flanks He had no operation and made an uninterrupted recovery By a study of cross sections we made out that the fragment had passed through the perirenal fat striking the cortex of the left kidney, it then skirted the upper border of the pancreas, traversed through the lesser sac of the peritoneum and the gastro-hepatic omentum above the lesser curvature of the stomach It then pierced the liver and diaphragm, to come to rest on the sixth rib junction half an inch to the left of the right pleural reflection and immediately below the pericardium

Moribund cases —It is difficult to state the signs that are relied upon in forming an opinion that a case is hopeless The term is justified by the fact that the average duration of life in 33 moribund cases admitted here was under five hours, in spite of everything that was done to try to rally them. In most of the cases the pulse was imperceptible or almost so and in some cases where it could be felt it was irregular Many of the cases were suffering from complicating wounds of limbs or head As the general sensibility becomes more clouded tenderness and rigidity of the abdomen become less marked If a case is seen to be hopeless an operation should not be performed, as should they survive the operation death in these cases is much more painful

Another type of case in which operation should be avoided is that where the missile with or without passage through the abdominal cavity, has lodged in the vertebral column and caused lesion of the spinal cord Every case on admission is tested for paralysis of the lower extremities, even when the wound is in the mid axillary line or on the point of the shoulder In one rush of work we had seven spinal cases in two days in most of which the spinal lesion was undiagnosed before admission These spinal cases may have intense pain referred to the abdomen which might cause a mistaken diagnosis of a penetrating wound of the peritoneal cavity

Treatment

During a rush the order in which cases are sent to the theatre is of great importance Gut injuries are sent first, then the cases of suspected wounds of the solid viscera and lastly contour wounds. At these times one of us remains constantly in the receiving room as the order of cases for operation may have to be changed from time to time as this or that patient develops fresh symptoms As to the technique of the operation little need be said

SERIES OF 110 CASES OF LAPAROTOMY FOR WOUNDS OF THE ABDOMEN

“Result” col: R recovered D died. Vomiting, “Rigidity,” “Tenderness” cols: P present N not present P(h) present (hæmorrhage) P(ls), present (left side) P(rs) present (right side), NM not marked P(hy) present in hypogastrium L local

No	Result	Hrs. after Injury	Pulse	Vomiting	Position of entry wound	Rigidity	Tenderness	Injury found	Complications
1	R	4	88	—	Below and to left of umbilicus	P	P	Three rents in upper part of jejunum Bleeding from mesentery	—
2	D	4½	84	P	Right chest behind	P	P	Penetrating wound of right kidney Two holes in small intestine	Right hæmothorax
3	D	7½	100	—	Right buttock	P	P	Two holes in small intestine 14 in above cæcum Mesentery bleeding	Iliac bone smashed
4	D	3	109	P		P	P	Many holes in small intestine Three resections	Wounds of upper & lower limbs
5	D	14	80	P	Lower right chest	P	P	*Left kidney torn (nephrectomy) Spleen torn*	*Three ribs broken Old tubercle of lung*
6	R	5½	85	N	Transverse sub umbilical	P	P	Abdominal wall opened from right to left flank No injury to gut	Injuries to left forearm
7	R	7½	80	N	Below and to left of umbilicus	P	P	Ten wounds in jejunum Resection 20 in Hole in mesocolon	Fracture of left radius through and through wound
8	D	6½	72	N	Right iliac region	P	P	Wound of cæcum and transverse colon and ileum	—
9	D	14	96	P	*Left buttock*	P	P	Two holes small intestine. Hæmorrhage from intern. iliac	—
10	D	11	120	N	Left loin	P	P	Wound 3 in long 4 in below *duodeno-jejunal junction Bruising of left kidney*	*Much laceration of muscles of back*
11	D	12	88	P	Right rib margin in front	—	—	Right lobe of liver almost torn in two Much bruising of abdominal wall	—
12	R	3½	92	N	Left chest	P	P (ls)	Wound of and hæmorrhage from spleen	Penetrating wound of chest
13	D	—	112	—	Left rib margin; omentum prolapsed	P	P	Two holes in transverse colon Large rent in diaphragm through which stomach and transverse colon passed into left pleural cavity	—
14	D	22	80	—	Right rib margin omentum lacerated	P	P	Lower margin of liver smashed Three holes in small intestine	—
15	R	33½	104	P	Left buttock.	P	P	Wound of spleen and wound of small intestine	Peritonitis present
16	D	14	120	N	Right buttock	P	—	Wound of liver	Retro-peritoneal hæmorrhage
17	D	22	108	P	Right loin.	P	—	Wound of right kidney liver and diaphragm	Right chest penetrated
18	R	30	132	P	Left buttock	P	P	Wounds in cæcum and 8 or 9 holes in lower part of small intestine Resection 12 inches	Peritonitis present
19	R	48	88	N	Over left great trochanter	P (ls)	P	Muscles of abdominal wall torn through on left side omentum injured	Iliac bone fractured
20	D	15	—	P (h)	Below and to left of umbilicus	P	P	Twelve holes in small intestine One large hole in transverse colon, and two holes in stomach	Peritonitis
21	R	6	100	—	Left 12th rib behind	P	—	Left kidney penetrated Spleen torn (sewn with catgut)	Lower three ribs smashed
22	R	11	128 (vf)	P	Below and to left of umbilicus	P	P	Eight holes in jejunum (upper part) three wounds in great omentum	Wounds left thigh and right arm
23	D	11	115	—	Right buttock	NM	P	Seven holes in small intestine Appendix torn away	Wound of right leg Fractured right pelvis
24	D	17	148	NM	Right flank	NM	P	Wound in ascending colon Wound of right kidney	Retroperitoneal hæmorrhage (extensive)
25	R	6½	100	P	*Mid line below umbilicus*	P	P	*Five wounds in small intestine* one almost dividing gut Three holes in mesentery	Wound of face
26	D	7	106	P	Left buttock	P	P	One wound in small intestine Two wounds in descending colon	Wound of right calf Fractured ilium
27	R	3½	92	N	Right costal margin	P (rs)	P	Deep tear in right lobe of liver	Wound in back
28	D	3½	100	P (h)	Right chest	P	—	Penetrating wound of liver Tear 3 in long in stomach One hole in small curvature One hole in small intestine	Penetration of right chest
29	D	12½	100	P	Right buttock	P	P	Wound in small intestine	Peritonitis Wound of rt arm
30	R	6	90	—	Right epigastric	N	P	Missile passed down cutting through abdominal muscles bruising anterior wall of bladder and dividing urethra *No injury to gut*	Large pelvic hæmatoma.
31	D	6½	80	N	Left loin.	P	P	Spleen torn and bleeding removed Kidney torn and bleeding removed	—
32	R	6	92	N	Epigastrium	NM	NM	Through and through wound of right lobe of liver Much bleeding No injury to gut	—
33	R	15½	93	N	Left iliac	P	P	Hæmorrhage from mesocolon	Retroperitoneal hæmatoma.
34	D	17½	128	N	Left flank	P	P	Tear in splenic flexure Left kidney torn	Left thumb blown off Wound of scalp
35	D	6½	-	N		P	P	Four holes upper part of jejunum Two holes transverse colon.	Excessive retroperitoneal hæmorrhage.
36	D	16	98	N	Right chest.	P	P	Four holes in small gut. Tear of great omentum	Seven wounds of right leg
37	D	16	64	P	Right flank	P	P	Eight holes in small *intestine Resection Three holes* in colon Right lobe of liver torn	—
38	D	29	110	—	Right lower chest	P	P	Wound in diaphragm, liver and omentum	Right chest wound General *peritonitis*
39	D	28	—	N	Left of umbilicus	P	P	Two holes in jejunum one tear in transverse colon	—
40	D	34	112	P	Left flank	P	P	Four tears in small intestine Resection	Peritonitis present. Fractured left iliac bone
41	R	36	94	P	*Right of umbilicus*	P	P	Wound small intestine Hæmatoma in omentum	Gas gangrene in mesocolon
42	D	30	98	—	Right epigastrium	P	P	Many holes in small intestine (28 in resection) Hole *in ascending colon*	Gas gangrene in left thigh
43	D	36	106	N	Left flank	P	P	Hole in colon stomach and small intestine	Right iliac bone fractured Wound of right leg
44	D	60	124	N	Epigastrium	P	—	Tear in ascending colon	General peritonitis Bronchitis Died under stovaine *anæsthesia.*
45	R	32	100	P	Left of umbilicus	P	P	Two holes in jejunum Tear in transverse colon	*General* peritonitis present.
46	D	5	96	N	Right buttock	P	P	Three tears in small gut Two holes in rectum	Compound *fracture* of left tibia. Fracture of left iliac bone
47	R	8	106	P	Left buttock	P	—	Two holes in colon One tear in small intestine	*Left kidney lacerated*
48	D	6½	100	—	Left rib margin	P	P	Jejunum torn across Resection. Hole in transverse colon Sigmoid torn across	—
49	R	11	82	P	Left iliac region	P	P	Hole in jejunum Hæmorrhage into mesentery	Penetrated *left iliac bone*
50	R	12½	124	N	Left thigh	P	P	Several holes in cæcum Appendix inflamed	Retro peritoneal tissues opened up
51	D	6½	100	—	Right epigastric	P	—	Four inch rent in duodenum	—
52	R	5	126	—	Left iliac region	P (hy)	—	Two holes in bladder two in rectum missile leaving body through left buttock	—
53	D	6	136	N	—	P	P	Many holes in *small intestine (Resection) Many holes* in colon Colectomy Ileum implanted in sigmoid.	Left chest opened Empyema *subsequently drained*
54	R	5½	88	P	*Lt.* chest omentum & sm int. prolapsed	P	—	Four feet of small intestine cleaned and replaced Spleen lacerated and bleeding Splenectomy	Multiple wounds of leg
55	D	—	90	P	Left buttock	P	P	Much hæmorrhage into peritoneum. No lesion of gut found Wound of left kidney passing up through diaphragm to left lung	—
56	R	12½	100	—	Left epigastric.	P	—	Stellate tear in left lobe liver Much hæmorrhage Sewn up	Subsequent pneumonia
57	R	5½	96	N	Left lower chest	—	—	Hole in small intestine Lacerated wound of splenic flexure of colon Resection Omentum herniated	—
58	D	6½	108	P	—	P	P	Tear in colon Six separate holes closed Many holes in	

SERIES OF 110 CASES OF LAPAROTOMY FOR WOUNDS OF THE ABDOMEN—(*continued*)

Pulse" col (vf) very feeble (vs) very small (v so), very soft (vw) very weak (s), small

No	Result	Hrs after injury	Pulse	Vomiting	Position of entry wound	Rigidity	Tenderness	Injury found	Complications
59	D	14	118	N	Right epigastric.	P	P	One tear in small intestine Tear in diaphragm	Left pleural cavity opened. Lung collapsed
60	D	3½	100	N	Through and through flanks	P	P	Several large wounds in stomach (gastrectomy) Tear in colon Liver smashed up	—
61	R	4	88	N	Left flank.	P	P	Multiple tears in jejunum (2 ft resected) Two perforations higher up (sutured) Large tear in colon	—
62	R	7½	84	P	Right flank	P	P	Large wound of liver bleeding	Right pleural effusion (subsequently)
63	D	3	90	N		P	P	Two holes in jejunum Two holes in hepatic flexure of colon Wound of liver	Wound of right chest. Compound fracture right elbow
64	R	3	88	N	Right iliac region.	P	P	Multiple wounds small intestine (resection) Torn external iliac vein.	Compound fracture rt humerus and rt. thumb Vomited round worm
65	R	10	100	N	Right chest behind	P	P	Two tears in hepatic colon	Penetrating wound of chest

70	R	3½	88	P(h)	Left chest	P	P	Two large wounds of stomach Hole in diaphragm	Penetration left chest.
71	R	5	96	P(h)	Left flank	P	P	Two wounds of stomach Wound of left kidney	Urinary fistula since healed up
72	D	6½	120	N	Right chest.	P	P	Much bleeding from lacerated spleen. Splenectomy	Left chest opened up
73	D	10	50 (vs)	N	Right epigastric	P	P	Extensive laceration of liver with hæmorrhage	—
74	D	11	95	P (b)	Left flank.	P	P	Two holes in small gut Three in large gut	General peritonitis lived 10 days Died of broncho-pneumonia.
75	D	12	96	—	Right rib margin	P	P	Deep laceration of both lobes of liver	—
76	D	12½	93	N	Right flank	P	P	Transverse colon riddled Resection	—
77	D	12	92	N	Lt chest posteriorly	P	P	Laceration of spleen.	Left chest opened Wounds right arm.
78	D	2	—	N	Left and above umbilicus	P	P	Stomach torn from end to end Several tears in small gut. Splenic flexure (resection)	—
79	R	7½	80	—	Glancing wound of chest and right abdominal wound	P	P	18 in of gut prolapsed Two tears in jejunum one 1½ in long	—
80	R	3	80	N	Right flank.	—	—	Transverse colon divided three-fourths of its circumference One hole in small intestine	Fractured right ilium
81	D	9½	102	N	Right buttock.	P	P	Colon divided Several tears in small gut	
82	D	4½	80 (vso)	P	Right rib margin	P	P	Wound of liver Two wounds of stomach Multiple wounds of small intestine Kidney lacerated (nephrectomy)	—
83	R	6	84	N	Left buttock	NM	P	Three holes in sigmoid flexure	Fractured left ilium Wound right leg
84	R	5½	84	N	Left lower chest	P	—	Two holes in stomach size of florin Penetrating wound of liver	Fractured ribs left side
85	D	6	80	P	Through flanks Omentum prolapsed from each.	P	P	Large tear in stomach Large stellate wound of liver	—
86	R	4	100 (vw)	P	Right buttock	P	P	Small intestine almost divided. Much hæmorrhage	Fractured right ilium
87	D	2	80	N		P	P	Small intestine almost divided in two places Cæcum torn	Fractured right ilium Large retroperitoneal hæmorrhage
88	D	8½	104	N	Multiple	P	P	Six holes in small intestine Two holes in sigmoid	Wound of thigh. Wound of right hand
89	R	6	96	N	Left flank	NM	P	Two wounds in small intestine One hole in transverse colon One hole in omentum	—
90	R	8½	92	N	Right buttock.	P (rs.)	P (rs.)	Much retroperitoneal hæmorrhage Bladder opened on right side Peritoneal cavity punctured in two places No bowel injury	Multiple wounds of both buttocks head and right side
91	R	4	92	P	Umbilical region	N	—	Three holes in small gut	—
92	R	4	80	—	Right rib margin	P	—	Penetrating wound of liver Wound of right kidney	Large retroperitoneal hæmatoma. Wound of face hand and chest.
93	R	2	93	N	Left chest	P	—	Spleen torn and bleeding Splenectomy	Penetrating wound of left chest.
94	D	17	94	N	Left loin	P	P	Two holes in small intestine	General peritonitis Died of bronchitis tenth day
95	D	3	130	—	Left buttock	—	—	Small bowel prolapsed Multiple large holes in small intestine (resection) Sigmoid torn through	—
96	D	8	104	N	Right epigastric.	P	—	Two holes in small intestine Much bleeding from hole in mesocolon	Peritonitis present
97	D	8	93	N	Left flank	P	—	Wound 1½ in. long in splenic flexure	Wound right arm Hæmorrhage from axillary vein
98	D	11	84	P (h)	Left epigastric	P	P	Wounds anterior and posterior surfaces of stomach Wound of head of pancreas	Died fifth day
99	R	8	—	—	Left chest	P	NM	Wound of liver and spleen	Penetrating wound left chest Subsequent resection for empyema.
100	R	3	64	N	Left buttock	P	P	Hole in rectum Hole in small intestine	Penetrating wound right pelvic wall
101	D	5	81	P	Epigastric	P	P	Two holes in stomach Holes in transverse colon. Damaged left kidney	—
102	I	5	103	P	Left buttock	P	P	Six wounds as large as a shilling in small intestine. Hole in mesentery Bleeding	—
103	D	18	94	N	Left flank	N	N	Five holes in small intestine	Symptoms on admission extremely masked by morphia Wounds of left shoulder and forearm.
104	D	5	100	N	Epigastrium	NM	NM	Three holes in stomach Descending colon torn in two	Severe flesh wounds in both thighs.
105	D	6	80	N	Right buttock	P	P	Four holes in ascending colon	Fractured right ilium
106	D	9	105	N	Left loin	P	P	Two holes in stomach. Two holes in jejunum one almost complete Three holes in splenic flexure. Left kidney damaged	Multiple wounds in thighs and buttock
107	R	2	73	N	Left of umbilicus	L	L	Abdominal wall torn Omentum protruding and removed	—
108	D	5	103	N	Right buttock to left buttock	NM	P	Extensive retroperitoneal and intraperitoneal hæmorrhage No injury to gut	Sacrum smashed in two
109	D	14	[illegible] (s)	N	Right chest	I	P	Large wound in right lobe of liver	Penetrating wound in right chest. Right lung collapsed
110	D	2	[illegible]	N	Left iliac fossa	—	—	Yds of small gut prolapsed Gut torn through and lacerated in two places (two resections)	Wound of leg

A large incision is made nearly from ensiform cartilage to pubes A central opening is preferable to one through the pararectal line, even when the damage is on the flank, for one gets less bleeding in the parietes, also a better opening is produced for examination of the interior and the surgeon can commence with a less anæsthesia and before a complete relaxation of the muscles is attained If later in the operation there is any difficulty in dealing with such parts as the spleen or colic flexures, a transverse incision into the flank may be made, and it is surprising to note how well and firmly this subsequently heals

Blood is present in the peritoneal cavity in almost every case, but this may be disregarded and a routine examination made at once, first of the small intestine commencing from the cæcum, then of the large intestine commencing from the same place, followed by an overhauling of the stomach, liver, spleen, and kidneys The damage, as met with, is repaired Wounds in the intestine are sewn if possible rather than a resection done We have learned by experience that the mesentery may be separated from the gut for a distance of 2 or 3 inches without the blood supply of the bowel being impaired

Quickness and gentleness are the essentials of the treatment of abdominal injuries In sewing up, through and through salmon gut sutures are first placed in position and the peritoneum is closed with a catgut stitch In cases where the peritoneum does not come together easily, especially above the umbilicus, we bring it together with catgut passed through the peritoneum and rectal sheath The salmon gut sutures are then tied Time must not be lost in elaborate closing of the belly wall As a rule, it heals soundly and cleanly In three cases a part of the abdominal wall gaped open about the tenth day and had to be restitched, but no ill resulted, and the patients made good recovery

Saline is given intravenously on the table, if necessary, but not as a routine, as we have thought that bronchial secretion was increased by this measure

When the patient is sent back to the ward he is placed for 8 or 12 hours with the foot of the bed well raised Subsequently he is made to assume Fowler's position During the first few hours after operation every endeavour must be made to combat shock and to keep up an adequate blood pressure in the circulation To this end we employ subcutaneous or rectal saline injections, pituitary extract, and the judicious use of morphia For the same reason it is not wise to restrict for too long the giving of nourishment by the mouth

Thirst is always a distressing symptom, and frequent small drinks of water, albumin water, peptonised milk, or weak beef tea are allowed from the commencement Occasionally, due to atony, the stomach becomes over distended, and this is shown by frequent small bile-stained vomits Lavage of the stomach is then resorted to, generally with great relief to the patient

Results

The nearer the front the operating centre is situated, and the earlier the cases are brought to it, the higher will be the mortality owing to more patients arriving alive who would have succumbed if they had been transported farther back At the same time one hopes that more lives are saved Statistics of necessity must be somewhat fallacious, as the majority of patients have multiple wounds involving other parts of the body besides the abdomen.

The results of six months' work give the following figures —

Total number admitted with abdominal wounds, 263
Recovered, 136 = 51 per cent Died, 127 = 49 per cent
Total number admitted "with penetration," 180
Total number on whom a laparotomy was performed, 110
Recovered, 46 = 41 5 per cent Died, 64 = 58 5 per cent
Laparotomies performed where wounds of solid viscera only were found, 21
Recovered, 13 = 62 per cent Died, 8 = 38 per cent
Laparotomies performed for injuries to hollow viscera only, 62
Recovered, 22 = 35 5 per cent Died, 40 = 64 5 per cent

The following analysis gives the relative frequency that the different organs were wounded in our series of laparotomies Stomach 14, small intestine, 60, large bowel, 40, rectum 3, liver 24, spleen 11, kidney, 14, bladder, 3

Note —Wounds of the abdomen, though involving the viscera, that were not treated by a separate median incision are not included as "laparotomies" in the above series

We feel we owe a debt of gratitude to Surgeon General Sir Anthony Bowlby and Colonel Maynard S Smith for much encouragement and advice in our work, and to Surgeon-General Bruce Skinner for help and support given us on many occasions

THE SURGERY OF AMPUTATION STUMPS,

BASED ON THE EXPERIENCE OF 2000 CONSECUTIVE CASES[1]

By G M HUGGINS, F R C S Eng,
TEMP CAPTAIN, R.A M C SURGICAL SPECIALIST, PAVILION MILITARY HOSPITAL, BRIGHTON

The surgery of amputations has entered a new era with the war There are various reasons for this development First, it must be remembered that in the experience of this generation modern aseptic methods meant a negligible number of amputations Then, the experience of the past generation of surgeons (who were of necessity masters of the art) is not really applicable to the present circumstances The old surgeons planned their operations essentially for speed and for use of peg limbs, and the classical operation for the foot belonged to an age when artificial joints had not been introduced Nowadays the aim of an amputation must include the ultimate fitting of the often delicate and complicated artificial limb which the modern instrument-maker produces

Primary amputations are performed to arrest infection, and so to save life Further operation, or radical treatment, is commonly necessary in England to prepare or improve the stump, so that eventually a satisfactory limb may be fitted to it The aim of this article is to elucidate this secondary treatment—that is, the preparation of stumps for artificial limbs—and is based on the experience of nearly 2000 cases which I have seen at the Pavilion Hospital, Brighton At the same time these considerations will give a basis for action in the case of the primary amputations

Classification of Cases

The cases seen at the Pavilion Hospital have been amputated two months to two years before coming under my care, and may be roughly classified as follows (1) Good stumps not ready for an artificial limb, (2) unhealed stumps from primary amputations, (3) sequestrum formation, (4) sinus, (5) bad scars and eczemas, (6) pain or tenderness, and (7) joint contractures Three months must be taken as the minimum time in which an amputation stump can become ready for fitting an artificial limb, and then only if a tight bandage has been worn and massage used daily The bandage and the massage accelerate the shrinking of the stump

Unhealed stumps are, as a rule, the result of the so called guillotine amputations An amputation of the guillotine type, or one in which the flaps have not been stitched up, should be treated with continuous skin extension from the earliest possible moment until healed or operated on again, continuous extension will almost cover a guillotine stump in a few weeks

Every infected stump, after healing is well advanced, suddenly shrinks and the skin becomes loose, when this occurs the time has come to re-fashion the stump The length of time varies with different stumps, but two to three months is a usual time for the thigh, it may be longer If this time is chosen it is sometimes possible to remove the scar and bring the skin edges together without shortening the bone It is hardly ever necessary to remove more than half to one and a half inches of bone The importance of a few inches in length of the bone cannot be over-estimated in most amputations The other advantage of waiting is the improvement in general health and the higher resistance to infection that the patient develops

I have been very much struck, in studying the medical history of the cases under my care by the large number of bad stumps the result, as far as one can judge, of operating on guillotine stumps within two months of the original amputation It would appear that the risk of infection is much greater in the early days, either because the infection is more virulent or the patient's resistance is lower or both At any rate, the very large number of cases suffering from necrosis of bone that I have to deal with at the Pavilion Hospital are almost all in stumps that have been shortened within two months of a guillotine amputation, and, further, in my own cases where I have to shorten guillotine stumps (which I now postpone until the local and general condition indicates that the time has arrived for operation), although sepsis is met with from time to time, it is never of such a nature as to cause necrosis of bone, and, except in two cases, I have not been obliged to remove more than two or three stitches for irrigation and drainage Even if necrosis of bone does not occur, severe sepsis leaves a bad irregular surface where long flaps with muscles have been used, or a large scar adherent to bone where skin flaps only have been used In both cases further operation is often necessary

---

[1] Abstract of a paper read before the Brighton and Sussex Medico-Chirurgical Society

Sequestrum —No stump is ready to send to the instrument-maker until it has been radiographed, as it is quite a common thing for a stump to heal and yet contain a sequestrum, with the result that as soon as an artificial limb is worn an abscess forms and a sinus results If the sequestrum is small at least two pictures should be taken to enable the surgeon to know where it is, so that it can be removed with the least possible damage to the stump Sequestra in stumps are generally buried in new bone thrown out from the end of the shaft The amount of new bone is often very large, and I have had to remove as much as an inch of new bone before coming to the sequestrum New bone which is cancellous can be chiselled away freely, but the shaft of the bone must on no account be injured, because the inflammatory reaction following this operation is often very severe, and should the shaft be injured there is a risk of further necrosis

Sinus —Sinuses in stumps are due to (1) silk ligatures, (2) necrosis of bone (3) foreign matter, such as metal, or (4) long septic tracks in scar tissue which are unable to close from imperfect drainage and low vitality I always use a crochet-hook instead of a probe in examining a sinus, and with this very useful little instrument ligatures or small sequestra may be removed. It is not advisable to operate on a sinus with a view to removing ligatures unless repeated attempts with a crochet-hook have failed. When silk is the cause of a sinus there are often several pieces In one case 17 silk ligatures were discharged from a thigh stump in the course of three months Four or five is a more usual number, and a great deal of harm may be done to a stump by exploring for silk. Silk should never be used for ligatures in operating on amputation stumps, for it is the cause of 40 per cent. of the sinuses I treat, and causes prolonged convalescence and needless suffering

The second and third causes of sinus, necrosis and foreign material require localising by the aid of X rays, and the remarks made under sequestrum" apply

The fourth class of case, the long septic track in scar-tissue, is difficult to diagnose, and can only be proved by exploration of the sinus If nothing in the nature of a foreign body is found I place the case in this class and excise the skin round the sinus and remove the deep part of the scar and then sew up the wound Packing the wound and attempting to obtain healing from the depth often leads to a bad puckered scar, the stitches can always be removed if necessary

Pain in the stump or tenderness of the stump —Causes (1) Nerves adherent to the scar, (2) bulbous nerves, (3) sequestrum in new bone in a healed stump, (4) spurs of new bone, (5) chronic abscess Nerves adherent to the scar (the result of not shortening the nerves at the time of amputation or when shortening the stump) always have to be removed and in this connexion it is important to remember that a nerve such as the internal saphenous is as important as the great sciatic both in the thigh and in the leg As a rule removal of the nerve from the scar is the best procedure but in the case of short leg stumps I always remove the popliteal nerves at the bend of the knee and the internal saphenous in Hunter's canal, for by this means there is no fear of the new cut end receiving pressure from the bucket and so becoming tender again Should an amputation stump suppurate there is grave risk of the nerves becoming adherent and painful even if shortened Bulbous nerves not adherent to the scar as a rule become painless in about three to four months and so I do not remove them until I have waited this length of time The converse is true and bulbous nerves not tender or painful sometimes become so after three or four months and when this occurs I remove the bulb as the prognosis is bad without operation One bulbous nerve may cause extensive symptoms such as a large area of hyperæsthesia, and in one case it gave rise to epileptiform fits These occurred over a period of some months but ceased altogether after removal of the bulb

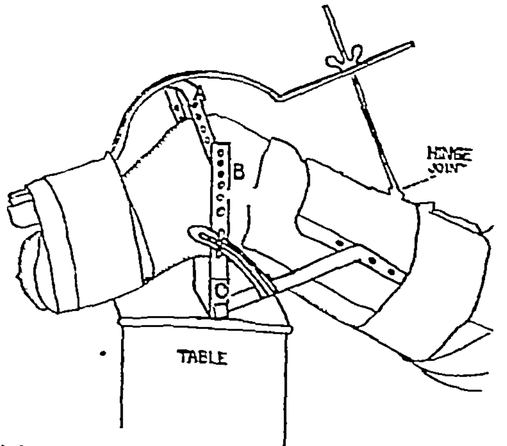
Spurs of new bone —Spurs of new bone are common, and every now and then cause pain and require removal. The large amount of new bone formation in stumps that have been infected is striking, and it often takes on fantastic shapes and follows muscular attachments and sinuses Spurs running into the adductor muscles are the most common and it is in this situation that I have sometimes had to remove them on account of pain. It is important to be sure that the pain apparently due to the spur is not caused by a bulbous nerve, as in my experience it is rare for a spur alone to cause pain

Chronic abscess —In these cases the diagnosis will generally be bulbous nerve, but instead of a nerve a small abscess will be found sometimes round a ligature and sometimes with no apparent cause.

Bad scars and eczema —There are two classes of unsatisfactory scar—one due to insufficient covering of the bone end and the other to too much covering—in stumps that have been infected. In the first group if the scar is very large and liable to ulcerate it is necessary to excise it after skin extension has been used In the second group, if the edges are very puckered and turned in the scar is liable to eczema, and in leg stumps, after wearing an artificial limb, it is apt to break down from the softening which results from the sweat decomposing In excising the scars of the second class it is important to re-fashion the deep parts as well as the skin, otherwise the condition will relapse when healing occurs

Joint contractures —In a great number of cases which I see the following conditions are found (1) Flexed knee, (2) flexed and abducted hip, (3) adducted shoulder

Flexion deformity of the knee-joint, if only of a mild degree, is cured with massage and a back splint If more severe and of several months' standing, I use a splint made for me by Major Lightfoot, of the Hove War Hospital Supply Depôt and by means of this splint most flexed knees can be straightened If this fails the posterior capsule of the joint should be divided with a tenotome Tenotomy of the ham strings alone is not likely to correct the deformity if adequate splinting has already been tried without success



Splint for straightening flexed leg stumps —Splint applied to flexed leg stump The joint at C, and the ability to alter the length of the bars C B and B A, enable the splint to be centred over the knee-joint in any case The splint was designed to be fixed in plaster-of Paris

The deformity of flexed and abducted hip is usually corrected by massage and movements, but in the event of failure tenotomy of the tensor fasciæ femoris should be done and in some cases it is necessary to divide the anterior portion of the capsule of the hip-joint. The correction is maintained by a plaster-of Paris spica. An artificial limb can never be worn satisfactorily with a flexed thigh stump

Adduction deformity of the shoulder is treated with massage and movements, if these fail an anæsthetic is given and the condition forcibly corrected, the correction being maintained for some weeks in a plaster of Paris splint

Joint contractures can, and should be prevented by daily movements of the joints likely to become contracted, aided by bandages and splints It is impossible to splint properly, or to move a stump when the nerves have been left unshortened as the pain is too great.

Considerations guiding Shortening of Amputation Stumps

In shortening stumps I only use skin flaps, and the flaps used are shorter than the flaps generally recommended in text-books Too much skin gives a bad flabby stump, which becomes ultimately badly nourished I never now use muscle in the flaps, as, rather than being an advantage, it has several disadvantages, in practice a guillotined arm stump is often better than the stumps resulting from skin and muscle flaps When shortening amputation stumps I am guided by the following considerations —

The Foot —A Syme amputation with bone section a quarter of an inch above the articular surface of the tibia and with all the bony projections rounded off, gives a stump short enough to fit an artificial ankle, and is end bearing This must be regarded as the best amputation that can be done A Pirogoff stump is too short to use as a peg and too long to fit an artificial foot to, it is an amputation of no practical value, and should never be done The stump of a Chopart, as a rule, becomes deformed, and even if it does not it cannot compare with a Syme, owing to the difficulty of fitting an artificial appliance A guillotine Chopart as a primary operation leaves the necessary material for doing a satisfactory Syme later

The Leg —Amputation in the middle third of the leg, at the lower end of the prominence of the calf, using a long anterior and short posterior flap gives the most serviceable stump below the knee with the exception of a Syme Amputations in the lower third of the leg give a weak scar liable to ulcerate in winter, and they necessitate the wearing of a clumsy and heavy artificial limb Amputation at the seat of election should not be done if greater length can be given, and never merely to improve the scar unless end bearing can be obtained for certain, in the absence of end bearing the importance of an extra inch of lateral bearing cannot be overestimated Unless two fingers can be placed side by side on the inner side of the posterior surface of a leg stump when flexed the stump is too short to use a below knee artificial leg and a kneeling leg will have to be worn When shortening a leg stump it is advisable to do a supracondylar amputation, unless this length of stump can be obtained

The Knee —Amputations through the knee must be well covered, and it is unusual for enough skin to be available, for if enough skin is available a short below-knee stump could as a rule, be obtained The patella should always be removed in amputations about the knee The best amputation about the knee is through the top of the condyles, rounding off all bony projections and if this be done an end bearing stump is made which is short enough to allow an ordinary artificial knee joint to be fitted Stokes Gritti s amputation is an unnecessary refinement unless the bone section has to be made above the cancellous part of the femur and then it should be used to make the stump end bearing

The Thigh —Every inch of the femur above the condyles is of the utmost value until the upper third is reached In this situation, unless two and a half inches of bone below the lesser trochanter can be saved a thigh bucket cannot be used Therefore it is best to amputate through the neck of the femur, when this amount of bone is not available, a less severe amputation that will be satisfactory is just through the junction of the great trochanter and shaft

The artificial leg for a hip joint amputation is a sound practical appliance and can be fitted to a subtrochanteric amputation It is not satisfactory with longer stumps or with a long fleshy stump such as the Furneaux Jordan It is important to consider this before interfering with a guillotine stump in the upper half of the thigh. I often see nice-looking stumps the result of re-amputation which are too short for a thigh bucket and bad or impossible for a hip bucket and moreover some of them are covered with muscle showing that more bone could have been saved A conical stump can no longer be regarded as necessarily bad, as they are often satisfactory

The Wrist and Forearm —One movable finger is better than any artificial appliance that can be obtained Through wrist amputations must now be regarded as satisfactory Every inch of bone from the lower end of the ulna to within three inches of the upper end of the ulna is of value, less than three inches of ulna cannot be made use of, and so, when compelled to re-amputate a forearm stump unless three inches of ulna can be left it is best to do a supracondylar amputation, removing the supracondylar ridges

The Arm —Every inch of humerus above the condyles is useful Guillotine stumps make better stumps than amputations where muscle is placed over the end of the bone Unless one and a half inches of bone below the anterior axillary fold can be saved the shoulder joint cannot be used The shoulder joint artificial arm does not press on the stump, and so it is not necessary to remove bulbous nerves from these very short stumps unless they give rise to neuralgia.

Summary

No secondary amputations should be performed in cases of guillotine amputations until all œdema has disappeared and skin extension has been employed for six weeks

Guillotine amputation stumps above the middle of the leg or middle of the thigh should never be shortened until healed unless it is decided that the knee joint or hip must be sacrificed When shortening has to be done the minimum amount of bone necessary for utilising the joint above should always be borne in mind A guillotine amputation may make a satisfactory stump in the leg and thigh and almost always does in the forearm and arm without further re amputation

Bone in a stump does not necrose unless infected. Delay in shortening stumps reduces the risk of infection, because infection is not in the wound only but in lymphatics leading from the wound The amount of matting round the vessels leading to or from an amputation stump is very striking

Silk should never be used for ligatures in operations on stumps Amputations should be done by skin flaps only and no muscle should be utilised in the flap, the pad of fibrous tissue formed over the end of the bone from the organising clot being all that is necessary All nerves, and not merely the main nerves, must be shortened at the time of the amputation or re amputation

To prevent deformity, daily exercising the joints and the employment of splints and bandages are essential measures in preparing the stump for the artificial limb

A good Syme amputation leaves the patient with little disability, and amputations through the tarsus should never be done as a secondary operation

KORSAKOW'S PSYCHOSIS IN ASSOCIATION WITH MALARIA

By HILDRED CARLILL M A., M D Cantab,
M R C P Lond,

ASSISTANT PHYSICIAN WEST END HOSPITAL FOR DISEASES OF NERVOUS
SYSTEM LONDON AND SEAMEN'S HOSPITAL, GREENWICH LECTURER
IN MEDICINE LONDON SCHOOL OF CLINICAL MEDICINE ETC.
TEMP SURGEON R.N NEUROLOGIST TO ROYAL
NAVAL HOSPITAL HASLAR.

During the war a large number of patients have been seen who have lost their memory This is not infrequent among those who are suffering from the effects of shell shock In other cases the condition has undoubtedly been simulated in order that the patient may have a better chance of escaping from uncongenial service or it has been assumed to excuse some breach of discipline A few patients have come under observation in whom loss of memory was one of the signs of dementia paralytica and in several others it occurred after concussion of the brain. In the latter class of patients it is not uncommon to find that the memory of the accident or of the circumstances which lead up to it is completely lost In several of the forms of alcoholic insanity, for instance in delirium tremens and in chronic alcoholic poisoning it is common to find that the memory is defective It occurs too in some forms of senility and also after attacks of epilepsy

Among these various conditions there stands out prominently that form of loss of memory which was described originally by Korsakow as occurring in patients of alcoholic habits who showed also signs of peripheral neuritis The condition was known as the polyneuritic psychosis. Frequently, however it could not be proved that alcohol took any part in bringing about the disease and later it became established that other illnesses, such as typhoid, malaria, diabetes arsenical poisoning &c all of which are at times associated with peripheral neuritis may give rise to the particular peculiarities described by Korsakow Furthermore many cases are on record in whom neither alcohol nor peripheral neuritis appeared to have any part and it is agreed at present that, while the typical cases are met with in alcoholic patients with neuritis, similar symptoms, which are indistinguishable from them, may be met with occasionally without neuritis and without alcoholism

The essential features of the disorder are loss of memory for recent events and difficulty in concentrating the attention The mental disturbance is one mainly of confusion of thought, disorientation and forgetfulness The patient loses the power of keeping events in their chronological order, and he constantly transfers to the present experiences which belong to the distant past He lives in a state of reminiscence

The following account is that of a patient who showed this condition He was a stoker, aged about 45, and he was admitted to Haslar on Nov 6th, 1916 The few notes which he brought with him showed that he had been admitted to hospital in Bombay on Oct 15th, 1916, and later to the 15th General Hospital at Alexandria The notes stated that when he arrived at the latter place he was very anæmic and had œdema of the lower limbs as high up as the lumbar region, and that this condition had been present for six weeks The urine showed degenerated hyaline and epithelial casts, but neither albumin nor blood was detected

When he arrived at Haslar on Nov 6th there was no œdema and the urine was normal He was very weak and anæmic, but no disease was detected except some recent gouty arthritis of his left wrist Gout was also detected in the right ear and in the great toe on the left side The red cells numbered 4 650,000 and the leucocytes 10,000 per c mm Of the latter 52 per cent were polymorphonuclear cells and 46 per cent were lymphocytes He was observed from the first to be rather dull mentally

On Dec 10th his temperature went up to 104° F suddenly and malarial rings were found in his blood by Dr P Fildes The attack rapidly subsided with the administration of quinine and on Dec 14th he was transferred to the neurological department for further observation of his mental condition For the notes already given I am indebted to Surgeon T G Gibson, R N, under whose care the man had been

In his story the patient told us that he was born on June 10th 1866, that he lived at a certain address at Fulham and that he had a daughter aged 12 years He said also that he had seen his wife recently at the hospital These statements it was not easy to disprove at the time, and indeed the idea of attempting to disprove them did not occur to us then Later, however, when he told us that the year was 1899, that King Edward was reigning, and that the war was between England and some field force and had been going on for four years, it was evident that we were dealing with some serious form of amnesia

The man was well nourished, but pale, and he looked a little simple He spoke quietly and politely and said that, with the exception of the pain in his wrist he felt quite well He told us that he had suffered frequently from intermittent fever" and that his last attack was about three months ago, when his temperature was 104° He said that he was ill for a week

He told us that he was for eight years on the active list and that he then became a labourer, implying that he had become a reservist and that he had been called up for the war This was supported by the fact that he was wearing a well grown moustache which he said he had let grow for some time He said that he had not been in action He did not know the name of the hospital, and his ideas about the war were hopelessly confused, but he was able to do sums well and he read intelligently He constantly stroked his moustache and chin with his hand He did not appear to be worried particularly about his loss of memory, but he recognised that matters were not as they should be He kept to himself a good deal, but appeared to be quite happy and contented

He remembered having been at Bombay but had no recollection of his illness there or of the swelling of his legs He could not tell us anything about his voyage home or about Christmas a fortnight before He stuck to his statement that King Edward was on the throne, but he could not give the name of the Queen or of the Premier When he was at a loss for a reply he *used to say* that he did not "read the papers carefully enough for that" He knew that Lord Roberts was in command during the Boer War and said that he expected that he was still "somewhere on the frontier" but he would not hazard which frontier he referred to He knew where he had been to school, and said that he was in the sixth standard He recalled that he had been engaged to be married for about a year He knew all about the circumstances associated with the relief of Ladysmith, but he did not know the name of Sir George White even when it was mentioned in conversation He said that he was a bald man and that he knew his photograph well When he was reminded about the battle of Jutland and of the Falkland Islands he appeared to recall them, but he remembered nothing about them For instance he did not know between which peoples the battle of the Falkland Islands was fought, but he thought that "England was there He remembered that the Boer War was between England and the South Africans, but he knew nothing at all about the Jutland battle, and when pressed for some information about this battle he said that it was at sea and in the air, between England on one side and some country whose name he could not remember on the other He said further that it was a kind of bombardment, and that Lord French was in command there, just as he had been at the Falklands, "because they must have had some troops there" He remembered the Diamond Jubilee, and thought that it took place in 1887 Later on, when pressed for more information about the war, he said that it was between England and the Balkan States

On examination his gait was seen to be normal and he had no tremors The spleen was not palpable His systolic blood pressure was 140 mm Hg He had no headache and the urine and viscera were normal His weight was 9 st 13 lb There was no evidence of alcoholic excess, nor was there any reason to suspect it His blood on Jan 15th, 1917, contained 5 050,000 red cells and 10,300 leucocytes per c mm, and of the latter 63 per cent were polymorphonuclears and 34 per cent small lymphocytes The hæmoglobin content was 90 per cent

Nothing abnormal was detected in the central nervous system with this important exception he had a bilateral absence of his ankle jerks This was confirmed repeatedly at subsequent examinations The calf jerks were active There was no history of sciatica, nor was there anything else found to point to a past neuritis

The association of the mental condition with the absence of ankle-jerks clearly made it imperative to rule out dementia paralytica, in spite of the fact that he did not resemble a case of this disease The Wassermann reaction in the serum and in the cerebro spinal fluid was found to be negative by Dr Fildes, and the cerebro spinal fluid contained no cells

On Jan 20th his wife came to see him She brought her step daughter and two friends Several letters written to her at the address at Fulham which was given to us by the patient had been returned to us and finally his correct address was obtained from the Admiralty It was in Portsmouth, where he had lived for four years His wife told us that she had not seen her husband for nearly four years, when he was last on leave As far as she knew, his previous health had been good He had done 18 years' active service and had commissioned the *Pyramus* at the onset of war She thought that he was still in this ship and had been worried because she had not heard from him for some time The last letter she had received was from the Sailors' Home at Bombay during November, 1916 She had no knowledge that he was sick She said that he had been a labourer formerly and that she had been married for 21 years

The man recognised his wife and friends, but was not able to join in the conversation as readily as they wished He told them that he must have grown his moustache on his way *home* He caused considerable surprise by solemnly announcing that Lord Roberts and General Buller were in command at the battle of the Falkland Islands The following day, Jan 21st, he recollected having seen his wife, but thought that she had brought with her his little girl He was reminded that he lived at Portsmouth, but up to the last he said that he lived at Fulham and that he was going there on his discharge He was discharged to his home on Jan 22nd, 1917

The wife's story is put in here so that the reader will be in possession of the actual facts of his personal history before he reads the short list of the man's answers to various questions which is appended. It was very evident, during daily conversation with the patient, that he was living through the period of the Boer War over again His memory for past events was not perfect, but it was far better than that for events of the present time In a few instances, such as that of the intravenous injection his memory for events of the immediate past was completely in abeyance However, when his mistakes were pointed out to him he would sometimes avoid repeating them the next day In some cases, when he made correct replies to simple questions of fact, it is likely that he had been told the answers by the other patients

Jan 3rd 191 —What is the name of the King?—Edward or William
What is the name of the Prince of Wale ?—George
What year did you j in the Service?—1899
Who is head of the Army?—Lord Roberts or Lord Kitchener
When did the war start?—1890
What month is it? (January)—December
What Queen is reigning?—Queen Victoria.
Who is Prince of Wales? Prince Edward.
Where does the King live in London?—Buckingham Palace
How long have you been in hospital? (Two months)—Ten days
Who is head of the Navy?—Admiral Jellicoe

What was the name of his ship?—*King Edward.*
Who married Lord Kitchener?—No one
What is the name of Admiral Beatty's ship?—*King Edward.*
Have you been on the *Reserve List*?—Yes after doing 12 years service
When did you rejoin?—At outset of war
Where did you spend last Christmas?—Has no idea
What ship did you travel home in? (*Britannic*)—*Tyne*
Where did you spend Christmas?—At home.
Have you ever been in a decorated ward?—Yes in the present ward, but I do not know why it was decorated

On Jan 4th I asked him when he had last seen me, referring to his catechism of the 3rd He hazarded, "The day before yesterday, in the ward, at 11 A M," *but he did not know what* we talked about As a matter of fact, the interview was in Sister's cabin, and at 6 P M

On Jan 5th, at 10 A M, I gave him an intravenous injection of "914," with the idea of stopping future attacks of malaria He had never had any injections previously At 4 P M *he had no recollection whatever of the injection*, and when I asked him when he would like to commence his treatment, *he said that he would leave all that to me*

The mental characteristics of Korsakow's psychosis are clearly portrayed in this patient *It* was evident that the absence of ankle jerks and the mental confusion must be associated if it was possible to do so, and it was fairly clear that the abnormality of the reflexes was due to a peripheral neuritis, although no other sign of neuritis was present What was the cause of the neuritis? There was nothing to suggest alcoholism as the cause The only facts which we possessed were that he had gout, and that he had a proved attack of malaria while under observation There was no reason to think that his gout was the cause of the neuritis On the other hand, peripheral neuritis has been noted in malaria not infrequently, and Manson remarks in his book that loss of memory, partial or complete, appears to be a common accompaniment of peripheral neuritis of malarial origin The illness from which the man suffered in Bombay, when his lower limbs were swollen, may have been beri beri, in which neuritis is common enough, or it may have been malarial nephritis It is by no means certain, however, that nephritis existed at all We could not ascertain what this illness was, but in view of the fact that he had malaria (and probably *it was not his first attack) it seems not unreasonable* to ascribe his polyneuritis and the characteristic loss of memory to the disease described by Korsakow

THE TREATMENT OF DIABETES MELLITUS

BY R T WILLIAMSON, M D LOND, F R C P LOND,
CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY

THE following is a brief sketch of the line of treatment which I have carried out with much success in many cases of diabetes mellitus during the last three years Recently many new methods of treatment have been published, *some* of which are of distinct service Certain of these methods have, however, disadvantages and are occasionally followed by unpleasant symptoms The line of treatment briefly sketched in this article will, I think, be found *free from risk* if carried out in the class of cases indicated (To limit the length of this article many of the details of the treatment have been omitted)

A routine examination of the patient *is* first made, complications noted, and the abnormalities of the urine determined When certain complications (affections *of* the lungs, heart and kidneys, &c) are detected a special form of treatment may be required and a rigid diabetic diet may not be desirable Such cases will not be considered in this article

When the case is one of diabetes without these complications a diabetic diet will be usually suitable But the form of the disease must first be determined When the urine gives persistently a claret colouration with perchloride of iron, and if this is not due to drugs, and if *other* indications of decided acidosis can be detected, the case requires very careful and special treatment, *these cases* will be briefly considered at the end of this article

If then no complications can be *detected* which require a special form of treatment, and if the urine should give no reaction with perchloride of iron, and no other signs of decided acidosis can be detected, the following course of treatment may then be carried out.

Course of Treatment

I The patient is first placed on Diet I —an ordinary rigid diabetic diet, but with the addition of 3 oz. of white bread *daily*

II If the glycosuria is not checked in a short time (few *days*) the white bread is promptly replaced by a pure diabetic bread (free from starch, or only containing the smallest amount thereof), such as biogene bread and ponos biscuits protein bread, &c [1]—Diet II

III If this fails after a fair trial of 10 *or* 14 *days* the following Diet III is often successful if the patient is able to rest at home *on a sofa for a short time*

For *one week* only food is taken in small quantities every 2 *hours from* 8 A M to 10 P M and the foods are eggs, milk, cream, custard, coffee, tea, and beef tea The following is the diet sheet —

8 A M Tea or coffee with one tablespoonful of cream. One egg (poached buttered or boiled)
10 A M : One glass of warm milk (10 oz)
12 noon : Custard unsweetened (containing one egg and half a pint of milk)
2 P M : One glass of warm milk (10 oz.) or cream (1 oz.) in warm beef tea (10 oz.)
4 P M.: Tea with one tablespoonful of cream; one egg (poached, buttered or boiled)
6 P M : Cream (1 oz) in 10 *oz. of warm beef tea*
8 P M : One glass of warm milk (10 oz.)
10 P M : Cream (1 oz) in warm beef tea (10 oz.)

In this diet (or in the modification following) the patient receives daily 3 or 4 eggs, 2 to 3 oz of cream, 2 pints of milk, in addition to tea and coffee and beef tea

The various small meals may be changed in order or altered *if the patient* desires *Thus*, at 2 P M cream and beef tea may be taken in place of milk, and a glass of milk *at* 6 P M *in place of cream* and *beef tea* At 8 P M one egg beaten up and added to 10 oz of warm beef tea may be taken in place of the glass of milk, or a poached egg and half a pint of beef tea if the patient prefers At 10 a glass of milk may be taken in place of cream and beef tea Also if the patient prefer an egg (poached or boiled) and a glass of milk may be taken at 12 in place of custard

This diet often checks the glycosuria in a few days or by the end of the week. If the glycosuria is not checked by *the end of the week* the diet *may* be *continued for* a few days longer, but if it then fails it should be discontinued and the patient placed back on Diet II *for* a few days. If the Diet III has failed to check the glycosuria the patient may be placed on Diet IV of casein or biogene and cream

IV Diet IV *of casein or biogene and cream*

The patient is given for seven or ten days a glass of casein or biogene and cream with water every two hours from 8 A M to 10 P M The casein preparation lait-proto No 6 will probably be the most satisfactory for the majority of patients A cup of tea or beef tea, or both, may be also taken, if the patient desires twice a day

The mixture of casein and cream and water is *prepared* as follows One tablespoonful of casein, or lait-proto No 6[2], one tablespoonful of cream, mix well in a tumbler with a spoon, then add hot water (or cold if preferred) very gradually, mixing well until the tumbler is full (The fluid may be sweetened with saccharin, or flavoured with nutmeg if desired)

In place of *one* tablespoonful of casein *two* tablespoonfuls of biogene[3] may be used if the patient does not like the taste of the casein It should be *mixed with two* tablespoonfuls of cream and the water added as just described

Many patients take the casein or biogene quite well, others find both unpalatable, and some cannot take either *Lait* proto No 6 may be taken quite well when ordinary casein or biogene cannot be taken

If we wish to avoid using diabetic breads instead of following the order just indicated the trial of Diet *II* may be omitted and if Diet I fails Diet III. may be tried at once, or if the patient likes the taste of casein or *biogene*, and can be seen daily, Diet IV may be tried before Diet III (*at once after Diet I*)

I have found Diet III (eggs, cream, milk, beef tea &c, as indicated) of very great service, it is simple *palatable* and often very successful It can be taken by nearly all patients and it is less expensive than diabetic food. *It can* be usually taken quite well by patients who cannot take casein or biogene It is very useful in the case *of diabetic* children It is often very successful both in mild cases and cases of medium severity, and sometimes in severe cases , In some cases, like all other treatment, it fails It often removes the glycosuria promptly in a few days or a week, though an ordinary rigid diabetic diet had previously failed. After taking this diet for seven or ten days often the patient may then take ordinary rigid diet for a long period without glycosuria returning, though previously on such a diet the glycosuria had continued. Probably it is not so often successful as the treatment with casein or biogene, but if it fails the latter treatment may then be tried, or a combination of the two methods may be tried Diet III. or IV should be continued for seven or ten days only They are to be regarded as methods of dietetic treatment which are usually much more successful than an ordinary rigid diabetic diet in removing the glycosuria temporarily, and the after effects probably continue longer If later the sugar returns in the urine the methods may be repeated Diet IV may be successful when Diets II and III have failed In a few severe cases with persistent diacetic acid reaction in the urine Diet III. or IV removes the diacetic acid as well as the sugar, but they are not always suitable in such cases

---

[2] Can be obtained from Casein, Ltd., Sheepstone-lane, Battersea, London, S.W

[3] Can be obtained from Messrs Callard and Co. 74 Regent-street London, W

After Diet III or IV has been tried for seven or ten days the patient is placed back on Diet II if the glycosuria continues If the glycosuria has been checked then the Diet III. or IV is gradually changed. One ponos biscuit is allowed at 8 A.M and 4 P M with the egg and tea. One or two days later bacon and green vegetables and custard are allowed at 1 in place of the meals at 12 and 2 and later Diet V and then Diet II are allowed.

Of course, the Diets III and IV will not be successful in all cases but they are always worthy of a careful trial except when the urine persistently gives a marked claret colouration with perchloride of iron In these cases caution is necessary, and sometimes Diets III and IV are not advisable.

V If all the diets already described have failed to check the glycosuria, then for a short time a diet of suitable vegetables, eggs and fatty foods may be tried (Diet V)

Breakfast Coffee (or tea) with cream , eggs (buttered poached, or boiled), or tomatoes or mushrooms , suitable diabetic bread or biscuits butter *Dinner* Bacon cooked in any way Any of the following vegetables cabbage, cauliflower, Brussels sprouts, turnips, French beans, spinach, broccoli, boiled walnuts, asparagus, vegetable marrow, tomatoes, mushrooms salad, lettuce, cucumber, watercress, celery, radishes Custard. Suitable diabetic biscuits or bread *Tea or evening meal* Tea and cream , eggs (buttered, poached, or boiled), or Welsh rarebit, cheese , or salad lettuce, cucumber, mushrooms tomatoes boiled egg and spinach, watercress , suitable diabetic bread butter

Or the following diet may be tried for a short time —

Breakfast Tea or coffee with cream , one egg and tomatoes or mushrooms or spinach , also one ponos biscuit or other similar biscuit *At 11 a m* Two tablespoonfuls of cream in half a pint of warm beef tea *Dinner (12 30 or 1)* Beef or tomato soup or one sardine and one ponos biscuit Afterwards one or more of the following vegetables Cabbage cauliflower, brussels sprouts vegetable marrow, broccoli (curly green), boiled celery asparagus, French beans, turnips, tomatoes, mushrooms boiled walnuts Brazil nuts sliced and fried in butter Custard stewed rhubarb gooseberries or cranberries with cream *Tea (4 to 5)* Tea with cream tomatoes or asparagus or celery or mushrooms, lettuce, salad cucumber, jelly, one ponos biscuit *Supper* Beef tea and cream (as at 11)

VI If these diets fail to check the glycosuria then drugs may be tried The drugs which I have found most useful are sodium salicylate aspirin and salicylate of quinine These drugs may be given along with Diet II or I or V I have been able to *demonstrate clearly*[4] the distinct effect of sodium salicylate and of aspirin in diminishing the glycosuria in certain cases of the milder forms of diabetes and also in cases of medium severity Some patients take sodium salicylate better others aspirin.

The dose of these drugs has usually to be increased to 15 gr (or more) four times a day before definite effects are obtained and a careful watch should be kept for toxic symptoms It is better to use the *natural* salicylate In certain cases salicylate of quinine gr 3 or 4 or more three or four times a day has appeared to be of distinct service, though I have not been able to clearly demonstrate this by careful hospital observations as in the case of the two drugs just named.

VII Fast days are sometimes of service. On these days the patient fasts, and takes only tea or coffee beef tea or whisky and soda several times and no other food. In the less severe cases the glycosuria ceases on these days, but it often returns in a day or two It may, however, not return for many days, and occasionally for a considerable time it is much less than before the fast days But so very often I have found the results of little permanent value. A fast day once a week is useful in some cases, but I much prefer the treatment with the two-hourly fluid diets III and IV , described in this article. I also prefer these diets to the more prolonged fasting which is being so frequently carried out

When the patient suffers from insomnia or marked neurasthenia bromide of potassium (gr 30 at night, or 30 early in the evening and 30 late at night) is suitable Overwork, mental strain and worry often increase the glycosuria, and should be avoided as much as possible

If none of these diets or treatments check the glycosuria, then we must be content if we can diminish it by the various treatments described After a time it is well to allow a small amount of white bread or milk, or both especially if the urine should give a persistent reaction with perchloride of iron

In some cases the most careful treatment fails , in others it is successful for a shorter or longer period and then fails But in some cases it is successful for many years, or even to the end of life.

If we have checked the glycosuria by diet or drugs, then Diet II may be allowed, and later Diet I. Still later more white bread is cautiously allowed, and then other starchy carbohydrates, if no glycosuria returns But it is always advisable permanently to forbid sugar and sweet foods containing sugar The urine should be watched and the diet made more rigid if glycosuria returns, and less rigid when the glycosuria ceases. In this way it is possible in some cases to keep the glycosuria in check for many years, or occasionally until the patient reaches advanced age and dies of some other disease

Treatment of Cases with Acidosis

When the urine persistently gives a deep claret colouration with perchloride of iron and other signs of acidosis are noted the outlook is unsatisfactory and very cautious treatment is desirable In spite of continued treatment such cases frequently advance to diabetic coma But sometimes by careful treatment this is checked for a long time and by treatment the perchloride of iron reaction may disappear and sometimes the sugar also, at least temporarily

The perchloride of iron reaction and other signs of acidosis may disappear in some cases when carbohydrates (3 oz. of white bread daily and three glasses of milk daily) are added to the rigid diabetic diet. In many cases after aperients the perchloride of iron reaction ceases for a short time Heavy oxide of magnesia gr 60 or more at night is a very suitable aperient or gr 30 three times a day in a little milk half an hour after meals After calomel, gr 1 three times a day and after treatment by an oatmeal diet (oatmeal porridge and milk three times a day) for two or three days the perchloride reaction may cease and also after the two hourly diet with eggs, cream, and milk, Diet III. or after the diet with casein and cream, Diet IV After these two Diets III or IV I have seen both the glycosuria and diacetic acid reaction to cease in some cases, but in many cases both diets fail

Diets III and IV are not suitable in some of the most severe cases of diabetes with persistent diacetic acid reaction in the urine In such cases I hesitate to advise them but even in a few of these cases I have obtained excellent results temporarily, especially with Diet III , and the urine has become free from both sugar and diacetic acid In many of these cases both Diets III and IV fail and they are not advisable in many of the very advanced cases If tried in these cases with persistent acidosis Diet III. is preferable to Diet IV and may be given in many of the less severe cases. When Diet III or IV is tried I often allow in addition for the first two days only a *small* amount of oatmeal porridge twice a day

---

[4] See the writer's articles on the Treatment of Glycosuria and Diabetes Mellitus with Sodium Salicylate Brit Med Jour., March 30th 1901 with Aspirin, Ibid., Dec. 27th 1902 Treatment with both Drugs Med Chron., May 1906 and Practitioner July 1907

It is curious that when the sugar excretion cannot be checked by the casein treatment or by Diet III in these severe forms of diabetes with acidosis, in some cases the diacetic acid disappears from the urine, whilst in others it remains much the same In a few cases the sugar excretion is arrested by the casein treatment, but the diacetic acid *remains in the urine*

To summarise briefly, we may say that in these cases with persistent acidosis the ordinary rigid diabetic diet is not suitable A small amount of carbohydrate (3 oz of white bread daily and three glasses of milk) should be added to the rigid diet, the meat should be restricted, fatty food and green vegetables are very suitable The bowels should be kept quite regular Citrate of soda 30 gr, increased to 60 gr or more three or four times a day, and 60 gr of bicarbonate of soda at night, in soda water or milk are of service, and larger doses may be given Alcohol (whisky or brandy) is probably of service

In course of time usually cases of severe diabetes with marked and persistent acidosis which cannot be arrested gradually advance to diabetic coma Severe constipation, physical overstrain, and mental shock or anxiety are all very liable to excite coma in these cases, and hence they should *be carefully guarded against If the diacetic acid and other* signs of acidosis cease then the outlook is, of course much *more satisfactory Then the treatment and Diets I to IV* already described may be tried strictly, as in cases of diabetes without acidosis

In this sketch of the line of treatment I have carried out in the last few years, I have not referred to many methods which have been recently much discussed and recommended Also I have not given many details of treatment I have tried to indicate only and as briefly as possible the line of treatment which I have carried out myself and found most useful

The treatment of diabetes is now much more satisfactory than it was a few years ago, and if carried out carefully and continuously, except in cases with persistent acidosis and even occasionally in these cases, the results are often excellent By one of the Diets I II, III or IV, or by drug treatment, &c, the glycosuria may often be arrested, at least temporarily and having been once arrested often it can be kept in check more or less, or kept small for many years, or even in some cases permanently

NOTE ON A CASE WITH SEVERE GASTRIC CRISES TREATED BY AACHEN METHODS

BY REGINALD HAYES, L R C P M R C S ENG

IN all cases of *syphilis of the nervous system* it is eminently advisable that prolonged inunction should be tried *It is best tolerated when given* with the sulphur water internally and externally as at Aachen If scrupulous *attention be paid to* detail in the administration no ill effects can follow and it is as a rule well borne The method in every particular has now for some years been carried out in this country, where the patient has the added advantage of keeping in close touch with his usual medical attendant The following are the notes of a case kindly referred to me by Mr Richard Lake

The patient, a middle-aged man, complained that for some weeks he had suffered, after the slightest exertion, from burning pains in the shins The *condition was getting worse* and he requested me to give him a course of Aachen treatment, as similar trouble in the past had disappeared after a visit to that spa Having only recently become aware even that any attempt was being made to reproduce the Aachen routine in this country, he was sceptical as to the *feasibility of carrying* out the exact technique, but was willing to give the time necessary for a thorough trial He was well nourished Refused a Wassermann test Urine normal Knee ankle, and wrist reflexes absent Pupils presented Argyll Robertson phenomenon Motor Walked cautiously—*slight* Rombergism, otherwise normal Sensory Areas of anæsthesia existed *over trunk* and limbs There was some deficiency in motor power of bladder and rectum

History—About 20 years ago he acquired syphilis, rash marked, glands in groin small Treatment Hutchinson's pills for six months, when he was pronounced cured and resumed his normal life He had no further symptoms until the end of 1902 when he found difficulty in singing choked without any obvious cause, and was troubled with giddiness. In 1903 he tried a holiday for some months, but on his return *felt no better*, was very depressed, and became unsteady on his legs from time to time, even falling down He consulted Dr Risien Russell, who diagnosed tabes and ordered rest in bed and general massage and inunction of mercury in axilla and groins daily for a few weeks This, in addition to KI internally, was persevered with for six weeks The patient felt better, and went away to the country for three months In May, 1904, he had a series of bad gastric crises, during which he nearly died Morphia and ether injections and feeding per rectum became necessary After this he was confined a great deal to bed, and in the intervals could only be said to "crawl about He was then advised to try inunction at Aachen *Going there in January, 1905, he was* placed under the care of a physician there, who confirmed the diagnosis of tabes, and on his advice the patient was submitted to 76 rubbings Shortly afterwards he had another bad attack of gastric crises and heart failure Again he nearly died, requiring morphia and ether injections and rectal feeding He improved, but after 32 more rubbings had a further alarming crisis In July, still another crisis occurred, necessitating rectal feeding, &c, as before Subsequently he had at Aachen, in October to November, 50 *rubbings 1906, 2 visits, 60 and 50 rubbings, 1907, 1 visit* 40 rubbings, 1908 2 visits, 40 rubbings each time, 1909, 1 visit, 40 *rubbings, 1910 to 1914 inclusive, an annual visit*, 40 rubbings on each occasion In 1915, no treatment, a Wassermann test done in the winter was negative

Recently, when he consulted me, the complaint was that he felt he was going back, as shown by burning feelings in the shins *after* quite a *short* walk, and a tendency to giddiness after sitting down I advised 40 rubbings with full Aachen technique These were carried out at his own house—a plan of great advantage in cases of this type As his wife had accompanied him during his many visits to Germany there was no necessity for explanation or excuse A few weeks afterwards his discomfort had gone and he had attained his usual level of health He expressed surprise that the technique with which he had become so familiar at Aachen could be reproduced in its entirety in London

This patient paid 13 visits to Aachen and underwent 693 rubbings It was *not until 108 inunctions* had been given that definite improvement was noted and the crises ceased He was never salivated, nor did he suffer from gingivitis His weight is now normal for his height, and has increased 3 st since beginning treatment His capacity for work and play is now considerable

SECTION OF ELECTRO THERAPEUTICS

New Method of Bullet Extraction —Heliotherapy and X Rays in the Treatment of Surgical Tuberculosis

A MEETING of this section was held on April 20th, Dr G HARRISON ORTON the President being in the chair

Dr A. E BARCLAY (Manchester) communicated through Dr R KNOX a further note on the New Method of Bullet Extraction, of which he gave a recent description—namely, by a specially designed, electrically connected pair of forceps to which a fluorescent screen was attached. Dr Barclay said it was difficult in the stress of war work, to assess the facts, but the instrument, when perfected, performed the extractions well and with but slight damage to the *tissues* But there were limitations (1) It could only be used in the direct line of the X rays, (2) it required experience and knowledge of X ray shadows to perform extractions safely and quickly, (3) the dangers due to prolonged exposures to X rays were not appreciated by many Army X ray workers who had *not* had experience of X ray therapeutics, hence such an instrument was not a safe one in their hands Dr Barclay's own experience with the apparatus had been successful He did not advocate the use of the *apparatus generally* in large military hospitals until the times were less strenuous and a proper *study could be given to it*

---

[5] In my article on *Diabetes in the* "Encyclopædia Medica" I have given details respecting diet drugs mode of life &c

Mr H J GAUVAIN read a communication entitled "Heliotherapy and X rays in the Treatment of Surgical Tuberculosis" He first outlined the modern conception of surgical tuberculosis The disease was a generalised one with local manifestations requiring very varied methods of treatment The question of the "soil" of the patient was of great importance, and every endeavour should be made to improve the resistance of the patient, so that his natural defences should be strengthened and fortified, in order to put him in the best position to overcome the disease Sunlight, he said, acted in two ways (1) directly on local lesions, and (2) indirectly by inducing favourable constitutional effects and benefiting deep lesions Direct action was beneficial (1) by the bactericidal effect of ultra violet light on superficial lesions, and (2) by the inflammatory response which exposure provoked This inflammatory response must be controlled, as, if unchecked, harmful and necrotic effects would be produced Evidence was cited to show that the ultra violet light waves most nearly resembling those found in the solar spectrum were of the greatest value Shorter waves might be injurious, in any case their beneficial action was not clearly ascertained and the danger of utilising artificial sources of light producing these short-waved rays was indicated Until more was known of their action they should be filtered off by suitable methods of screening All the beneficial effects were then obtained without exposing the patient to danger Exposure should always be carefully graduated The direct action of ultra violet radiation was limited to superficial lesions owing to the very small penetrating powers these rays possessed Their penetration might be increased by rendering the skin anæmic, but even under the most favourable circumstances their penetrating power was not great The greatest value of heliotherapy was associated with its remote effects, and light treatment for this purpose had not attracted the attention desirable The remote effects, Mr Gauvain said, appeared to depend upon the ability of the skin of the exposed patient to pigment adequately This pigmentation was produced by ultra violet radiation but was also dependent upon some factor inherent in the patient and varying widely in degree Equal exposure in different patients would induce very varying degrees of pigmentation and some patients would not pigment at all In these the direct effects of light therapy were produced as easily as in pigmenting patients, but the remote effects were unobtainable Sandy and red haired patients attacked by tuberculous disease often had little pigmenting power Their skins would freckle, but would often not pigment except with great difficulty Freckling was undesirable as its formation was not associated with any improvement He had noted that failure to produce pigmentation was often associated with latent tuberculosis, even though there were no clinical signs of active tuberculous disease Subsequent development and successful treatment of a hitherto unsuspected lesion were frequently associated with acquirement of pigmenting power which synchronised with rapid improvement both general and local This observation was, therefore of great prognostic value and corresponded to a somewhat remarkable extent with observations made on the prognostic significance of the von Pirquet reaction Mr Gauvain submitted a theory that the action of sunlight on man was to some extent on parallel lines with its action on plant life In green plants, the actinic rays stimulated growth, but it was the illuminating rays which viâ the transforming medium of the chlorophyll pigment effected assimilation In man while the ultra violet rays induced pigment formation it was probable that the remote benefits produced by sun treatment might be largely ascribed to the illuminating rays acting through the medium of the pigment There was much clinical evidence to support this and he had designed experiments which it was hoped would further elucidate this important question It was well known that the long waved rays had very great penetrative power, but in the absence of pigmentation they appeared to have little influence on surgical tuberculosis The physiological properties of these rays demanded careful investigation Pigmentation had an important protective rôle Once established prolonged exposure could be tolerated Pigmented patients suffered little from excessive heat or cold The effects of light treatment on pigmented patients were discussed The author considered that insolation should be regarded as an adjuvant method of treatment which accelerated and consolidated the cure It increased the patient's power of resistance It had a very marked tonic and pyschological effect It speeded up metabolic activity Oxygenation was increased but the respiration rate diminished, though the amplitude of individual respirations was greater There was increased elimination which was of value in the discharge of toxic products The effect on the blood stream was profound and increased formation of red cells, increasing hæmoglobin and leucocytosis had all been noted On even the deepest lesions marked improvement had been recorded Sinuses frequently dried up where other methods of healing failed Sequestra were often painlessly extruded The resulting cicatrices were often almost invisible and keloidal scars almost unknown Fibrous tissue generally when not needed was absorbed, and this property was of a special value in restoring mobility to healed joint lesions long fixed by fibrous ankylosis Viewed as a whole, patients did much better in the summer when exposed to sun treatment than in the winter In the after care of patients occasional courses of insolation should be prescribed Heliotherapy was undoubtedly of great benefit in consolidating a cure and reducing the danger of a relapse Heliotherapy in surgical tuberculosis was, in the speaker's opinion, contra indicated (*a*) for the remote effects in patients who have no pigmenting power, (*b*) in amyloid disease, (*c*) in certain acutely septic cases until improvement by other means has been first effected The indications for X ray treatment in surgical tuberculosis were next considered The importance of careful technique and selection of suitable cases was emphasised Iselin's table of tolerance was always observed The author summarised his observations as follows (1) X ray treatment was of great help in certain local conditions and synchronous with their amelioration general improvement is often maintained, (2) its value and applicability varied in different regions of the body, (3) it was useful in certain cases of sinus formation and in the treatment of many tuberculous ulcers, leaving supple, non keloidal scars, (4) it was especially valuable in certain cases of tuberculous adenitis, but the greatest benefit might usually be only anticipated if associated with other methods of treatment, and it was particularly useful where there was much periglandular infiltration and here formed a useful treatment preliminary to extirpation or aspiration, aspiration together with the use of modifying fluids to be preferred to extirpation, when possible, (5) it was most safely applied in tuberculosis occurring in the neck, elbow joint, and knee joint, (6) it was apparently helpful in certain cases of caseous abscess formation, (7) it was both unnecessary and undesirable in the treatment of abscesses which can be easily aspirated, and should not be used with abscesses which leak from an aspiration puncture which has resulted from faulty technique, (8) it was dangerous in abdominal tuberculosis and apparently of little value in costal tuberculosis, (9) possible untoward effects as the result of careless technique or too frequent exposure should always be borne in mind and guarded against, and (10) while of great assistance in the treatment of specific lesions other aids to treatment were often required and should be associated The paper was illustrated by numerous lantern slides and autochromes, one of the latter demonstrating the extrusion of sequestra during insolation

A discussion followed.

BRITISH SCIENCE GUILD —The eleventh annual meeting will be held at the Mansion House on Monday next, April 30th, at 4 P M, when Lord Sydenham will give an address on National Reconstruction

TAVISTOCK (DEVON) URBAN COUNCIL AND "MEDICAL ETIQUETTE"—At the last meeting of the Tavistock Urban Council a letter was read from the Local Government Board in reference to the free distribution of disinfectants The medical officer of health said he was afraid that no disinfectants would be forthcoming for the poor residents of Tavistock, because the medical officer of health was required to have a note from the medical attendant stating that a disinfectant was required and the medical men in the town "did not and would not, give these notes', he added that he doubted whether any other urban district demanded these notes A member remarked that it was some imaginary question of medical etiquette and he proposed that the council inform the medical practitioners of Tavistock that these notes should be adopted and this course of action was decided upon

Reviews and Notices of Books.

Military Surgery By DUNLAP PEARCE PENHALLOW, S B, M D Harvard, Chief Surgeon, American Women's War Hospital, Paignton, England, *Captain, Medical Corps*, Massachusetts National Guard, &c With an Introduction by Sir ALFRED KEOGH K C B, Director General, Army Medical Service With original drawings by the Author London Henry Frowde and Hodder and Stoughton 1916 Pp 432 Price 15s net

THE advent of the war has introduced many a surgeon, hitherto accustomed only to the injuries encountered in civil practice, to conditions almost unknown to him, not only in degree but in kind The variety and severity of the lesions produced in the present conflict have never been equalled in previous wars Fresh problems have presented themselves, at the solution of which hundreds of surgeons are working, many of them under difficulties inherent to war conditions, and there is little surprising in the fact that they have not all come to the same conclusions Unanimity under such conditions would not be a sign of healthy progress

We therefore owe a debt to those surgeons who, possessing a wide experience of the surgery of war, give the results of their labours to the world Dr Penhallow's position as chief surgeon to the American Women's Hospital in this country has given him ample opportunities of forming considered opinions, and in the volume before us he has recorded his conclusions regarding the best methods of treating wounds met with in the present war

The work is fully illustrated with drawings, photographs, and skiagrams, and the descriptions of treatment are sufficiently detailed to enable those with but little experience to follow them The varieties of projectiles are described, the infection of wounds is discussed in one chapter, gunshot wounds of soft parts are dealt with, and in other chapters the treatment of wounds of special structures, such as bones, joints, nerves, and blood vessels, such conditions as shell shock, gas poisoning, and trench foot also are considered

The importance of his views is much increased by the impression which the reader gains from Dr Penhallow's book of an extensive acquaintance with the writings of others in this domain of surgery, and of familiarity with the literature of the surgery of the wars of the past And this is well since on nearly every page matters arise in which there is room for discussion, and it will hardly be until the war is over, if then, that surgeons will be in a position to state with certainty what is the best practice to follow No surgeon at present sees the whole of the treatment of any long case, he may see it at an emergency clearing station or at a base hospital, or it may come under his care at a hospital in this country, but he will not see it from start to finish unless its course is brief indeed Time alone will give a clearer vision of what is the best treatment in prolonged and difficult cases

Dr Penhallow's book may be regarded as a serious contribution to this clearer vision, and it will prove of special value to the less experienced military surgeon, who will find it a trustworthy guide in carrying out his duties

---

Stati Ansiosi nelle Malattie Mentali By Dr GASPARE BERGONZOLI, Superintendent of the Provincial Asylum at Pavia Voghera Via Cavour 12 Pp 186—In every epoch and from very remote times the symptom group of anxiety and grief has been noticed in various organic and psychical maladies, particularly in those where, by its frequency and importance, it presents itself in a striking fashion The author, therefore, in this monograph draws attention to those forms of psychosis where anxiety occupies the principal part in the clinical picture of the disease so as to constitute a special variety, or other forms in which it constitutes an important symptom yet without changing materially the physiognomy of the psychosis After a brief historical review, the author describes a typical condition of "pantophobia" accompanied by symptoms of organic disturbance, of sensation, the circulatory and respiratory systems, &c, and then sketches phenomena of anxiety in organic diseases and psychoneurosis The bulk of the work, however consists in a careful, and elaborate description of "anxiety psychosis" in its various aspects and conditions of depression and obsession, followed by a chapter in which nine cases are portrayed with full clinical details The etiology and pathology of the condition are then discussed, and a separate chapter is devoted to its diagnosis, prognosis, and treatment, the author having obtained the best results from the administration of opium In an extensive bibliography of 358 items we only notice the names of Arnold, G Beard, Crichton, Robertson, S T Rucker, and Arthur Townsend among British and American observers, but the monograph is very complete and may be considered to be the last word on anxiety neurosis at the hands of our distinguished Italian colleague

Text book of Meat Hygiene By RICHARD EDELMANN, Ph D Third revised edition and authorised translation revised for America by JOHN R MOHLER, A M, V M D, and ADOLPH EICHHORN, D V S With 161 illustrations and five coloured plates London J and A Churchill 1916 Pp 462 Price 21s net —This third English edition of a well known work has been revised in several important directions Previously abundant references to German conditions, especially on the subject of the disposition of diseased animals, have now been replaced by exclusive reference to the rules and regulations governing the meat inspection of the United States Bureau of Animal Industry Further, since the publication of the second edition, reviewed in our columns of March 29th, 1913, alterations have been made in the regulations made by the United States, and the new régime forms an important portion of the subject-matter of this edition The new orders refer chiefly to the disposition of carcasses and to the recent measures of control adopted over the importation of meat The advanced attitude of a country like the United States in the important matter of meat hygiene is well worth studying, and apart from the practical chapters, which are of direct interest to the meat inspector, this book may safely be taken to represent modern views upon the whole subject.

Elementary Qualitative Analysis By BENTON DALES, Ph D, and OSCAR LEONARD BARNEBEY, Ph.D New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd 1916 Pp 205 Price 5s 6d net —Laboratory guides in qualitative analysis are fairly numerous, and it is only occasionally that an author is found to introduce any novel features This work presents, however, a few important departures which may justify its appearance The introductory chapters on the principles underlying qualitative analysis give a clear account of chemical changes, precipitation, the evolution of gases, and the like interpreted in the light of modern knowledge Dissociation into ions, reversible reactions, and the laws of equilibrium are discussed in a clear manner Coming to the group system, a new scheme is given for the detection of acids which facilitates this process, and the authors prefer to discover the acids first, as then, rightly enough, "the procedure for the bases can usually be abbreviated" The book reveals an experience of qualitative testing, coupled with a systematic presentation of facts, which should help to put the student in right paths

Text book of Elementary Chemistry By F MOLLWO PERKIN, Ph D, F I C, F C S, and ELEANOR M JAGGERS. London Constable and Co, Limited 1916 Pp 384 Price 3s 6d net —Chemistry in its applications to some of life's affairs is illustrated in simple terms in this book Only familiar things such as the air, water, chalk, sulphur, and certain metals are dealt with, but at the end of the story there appears a chapter on technical processes, illustrating the chemical principles underlying the manufacture of well known commercial products, as the aniline dyes, soap, glycerine, oils, and so forth It is doubtful whether the section on vegetable oils and animal fats will be clearly understood by the general reader when he has to face such terms as "monobasic" "glycerides" and "hydroxyls" There is a curious slip on p 166, where the authors state that "water is temporarily hard when boiling will not alter its hardness" On p 158 the student is asked to blow gently into a flask in which the loss of carbonic acid gas, by evolution from a carbonate, is being determined, it would clearly be more accurate to withdraw the residual carbonic acid gas by sucking it out, since the breath would deposit moisture, and so to an extent disturb the calculation The educational aim of the book is praiseworthy

A Great Advance in the Treatment of BURNS—*Slight or Severe*

AMBRINE

(Method of Dr BARTHE DE SANDFORT)

AMBRINE instantly alleviates pain
Promotes rapid healing
Forms a sure protection against infection of the Wound

Although the dressing with AMBRINE is seclusive and adhesive, it becomes after a short period non adhesive and can be removed without pain hæmorrhage or injury to the newly formed tissues The healing takes place without leaving scars or contractions

Supplied to The British Navy British Red Cross Many Ordnance and other large Works The French Ministry of War and Marine The French Red Cross The Italian, Belgian and Rumanian Governments. The French Railway Companies The Carnegie Trust Company, U.S.A. &c.

INDICATIONS

BURNS
NEURALGIA
PHLEBITIS
CHILBLAINS
SCIATICA
RHEUMATISM
VARICOSE ULCERS
NEURITIS
GOUT, &c

The *British Medical Journal* Sept. 2nd 1916.
Re AMBRINE TREATMENT

"The primary and quite incontestable advantages of the treatment are two: it is agreeable to the patient because entirely painless it is convenient to the surgeon because easily and quickly applied It is possible that the treatment would be useful in dealing with ordinary ulcers and in any case it is certain that the study of its application to the raw surfaces is worth pursuing "

NEOCAINE-SURRENINE

Neocaine is a synthetic product of French manufacture

A Perfect COCAINE SUBSTITUTE of Low Toxicity.

A White Powder, readily soluble in water

Analgesic power, duration, and rapidity of action quite equal to Cocaine

Toxicity less than one-sixth

Therapeutical effects identical with Cocaine (excepting as an exhilarant) for **Dental or Surgical local and spinal Anæsthesia, Lozenges, Snuffs, Ointments, &c**

Composition of Neocaine-Surrenine·

Pure Neocaine	5 c g
Acid Borate of Adrenalin (Takamine)	0 1 m.g

Pure Neocaine is also supplied

FORMS —Powder in capsules and phials Ready prepared solutions in Ampoules (various percentages), and Ampoules of sterilised liquid for making solutions

BIOSULFOL

(Assimilable Colloidal Sulphur.)

A GREAT ADVANCE IN SULPHUR TREATMENT.

Sulphur administered in this form by the digestive tract **is entirely absorbed** (90% in worst cases and 100% in others)

Biosulfol gives beneficial results, with which ordinary Sulphur medication, owing to its being only in part assimilated, cannot compare

INDICATIONS

Chronic Affections of the Pharyngeal and Bronchial Mucous Membrane

Chronic Affections of the Genital Mucous Membrane

Chronic Rheumatism (Polyarthritis deformans)

Various Affections of the Joints

Intestinal Intoxication

Skin Diseases

Mercurial and Lead Poisoning, &c

DOSAGE.

Biosulfol is prescribed in a one teaspoonful dose, to be taken during each of the two principal meals, pure or in water or milk It is quite palatable

CORYZA=RHINITIS

ACUTE CATARRHAL INFLAMMATIONS of the upper air passages popularly known as Catarrh or "a cold" as an independent affection or as an early manifestation of another disease are promptly and effectively relieved by the application of hot **ANTIPHLOGISTINE** over the entire naso-malar regions

Antiphlogistine reduces the swelling of the mucous membrane of the septum and lower turbinated bodies—the irritating excretion is lessened—the distressing sense of tightness—the "stuffed up" feeling and the pain over the frontal sinuses rapidly disappear—

Bronchitis—Pharyngitis—Tonsilitis—Laryngitis

respond quickly to the application of hot

ANTIPHLOGISTINE.

THE DENVER CHEMICAL MFG CO, BOW, LONDON, E 3

"Semprolin" Emulsion

with Iron

THIS preparation admits the administration of iron *for long periods* without digestive disturbance or constipation The iron, being in colloid form, is quickly and easily assimilated With Liquid Paraffin no habit is induced as with purgatives such as cascara, aloin, &c Gives excellent results in Anæmia, &c

In 8 oz and 16-oz Bottles

CONTAINING

Dialysed Iron	**20 minims**
Russian Liquid Paraffin, B P	**55%**

in each tablespoonful

LONDON SATURDAY APRIL 28 1917

The Calling Up of Medical Men of Military Age

THE attacks made by German submarines upon our hospital ships have determined the Government to take a step which as a matter of course must have been present to their minds for some time. It has been decided to call up every medical man of military age, and every practitioner in this category will become available for the Army by May 6th. The fact that the Germans had attacked relentlessly our hospital ships during the past fortnight was announced by Mr. BONAR LAW in the House of Commons last week, before the official statement, tragedies of the kind to which he alluded had received public announcement, and in the interval others have occurred with a sad loss of medical personnel. The torpedoing of the hospital ships made clear the necessity of establishing a large number of new hospitals over seas, so that the provision abroad of the suitable hospital personnel should enable the number of wounded returned home to be sensibly decreased. Accordingly, Lord DERBY has issued a letter from the War Office to the medical practitioners of the country explaining the situation clearly, and indicating that the extensive withdrawal from their practices in the country of medical men of military age must be answered by all who remain with offers to act in a general scheme of substitution, whereby the gaps in the home medical service may be filled as completely as is feasible.

The decision of the Government to call up medical men of military age will not come as any surprise to our readers who have been kept aware of the direction which events were taking. It has for some time been obvious that the demands of the War Office, which must be taken to be identical with those of the Army, for more medical officers could only with difficulty be met under any voluntary system. Under that system the country has received, and is receiving, the devoted assistance of thousands of medical men who have neither given heed to their *financial* present or their professional future, nor to the personal dangers of the medical soldier, as revealed in the ever growing lists of our dead and wounded colleagues. The Central Medical War Committee, the Scottish Medical Service Emergency Committee, and the Committee of Reference of the English Royal Colleges have all worked unceasingly to supply the War Office with medical officers, while watching over the interests of the civilian community at home, on whose maintained good health so much of our efficient conduct of the war necessarily depends. A large number of Local Medical War Committees have coöperated with the central bodies in recommending which of the practitioners in their localities should be taken and which should be left and their opinions often given in difficult and delicate situations, have, on occasion, been carefully revised by the central bodies, no pains being spared to balance the *pros* and *cons* and elicit the deciding factor in every instance. The deliberations of the Central Medical War Committee have been strengthened throughout by intimate relations with the Local Government Board and the National Insurance Commission so that individual exemptions of medical men by the statutory tribunal have been considered both on their own merits and in respect of any public claims. The result of all this hard and careful work, carried on from day to day over a period of 20 months, had begun to suggest that the voluntary reply of the medical profession had been given in entirety, and that further demands upon the practitioners of the country to take commissions would have to be based upon a scheme of general calling up of all those of military age, combined, it might well be, with modifications in the employment of medical officers whereby economy of material would be ensured. Just when affairs had reached this position came the unspeakable onslaughts by the German submarines upon the Red Cross ships, and the decision of the War Cabinet to call up at once under the Military Service Acts all medical men of military age followed immediately. Lord DERBY's circular letter, which we print elsewhere, conveys the information to the medical profession in complimentary terms.

The onus of responsibility is now removed from all medical men of military age, they are called up however, as a class and not as indistinctive citizens, and recent events have confirmed their central professional war committees in the resolve only to continue selecting doctors for military service if they are allowed to retain the decision how many and which individuals can be spared from civil work. To medical men above military age voluntary discretion remains, but in Lord DERBY's letter the hope is expressed "that every doctor over military age will immediately offer his services to the Local Medical War Committee of his area as willing to undertake any substitution work within his capacity which would help to release any man of military age who cannot otherwise be spared." Acceptance of this invitation will be easy for some men and extremely difficult for others, the considerations ranging themselves under such headings as age, health, locality, and equipment, and requiring no further analysis to make their force apparent to medical readers. We trust earnestly, and we believe, that those whom the call to substituted service finds in positions where response has less difficulty, will coöperate quickly with the Local Medical War Committees as to the effective utilisation of their services. It is said of all voluntary systems that the willing men are those who make the greatest sacrifices, and with this our profession, which has borne so much during the war, must not be reproached. There is need for promptitude in the giving in of names at the local centres, for the organisation of the measures possible for maintaining essential medical services, while meeting the demands of the Army, cannot be of a simple nature. Every hour will probably be of value.

The Surgery of the Abdomen
The Lessons of War

IN civil practice the surgery of the abdomen is of recent growth. It is well to remind ourselves of the time, not many decades ago, and therefore still within the memory of a large proportion of medical men in this country, when even the most experienced surgeon hesitated to open the abdominal cavity Reference to text books of surgery of 30 years ago will show that the surgeon then felt justified in washing and replacing a piece of bowel or other viscus protruding through an abdominal wound, or in tying the pedicle of a prolapsed spleen, but he did not venture to open the abdomen to examine the injury caused by accident or bullet A generation has changed all that The well founded respect of the surgeon for the peritoneum has given place to the conviction that however great the risk he runs of setting up a septic peritonitis in opening the abdominal cavity, the risk is as nothing compared with the danger of leaving untouched a perforated viscus The danger of infection from without is, under these circumstances, quite overshadowed by the danger of deflement from within, and the only course open to him is to explore the abdominal cavity and to close the wound in the viscus in order to limit the spread of the peritonitis which may already have started If this is true in civil practice it applies doubly to wounds in war, where the abdominal injuries are far more numerous and usually more severe The Lettsomian lectures on War Surgery of the Abdomen delivered by Colonel CUTHBERT WALLACE, consulting surgeon to the Army Medical Service, the concluding lecture of which appears in our present issue, and the analysis of abdominal surgery at a clearing station by Captain GERALD S HUGHES, R A M C, and Captain W A REES, R A.M C, record experience in dealing with the peritoneum resulting from many months' work in France The value of these papers to the surgeon rests on the fact that the opinions expressed are based on large experience and reasoned analysis of results

Under war conditions the precise nature of the fighting materially affects the methods of surgical treatment Success in the treatment of abdominal wounds depends principally on the ability to operate before much time has elapsed after infliction of the injury This condition is only granted when the hospital is within a short distance of the fighting line Such proximity has been possible during the fighting in France ever since the rapid retreat and the advance of the first two months were succeeded by a fighting front remaining practically fixed, with the result that casualty clearing stations become as well suited for abdominal operations as any base hospital Rushes of work there have been from time to time, and these are now occurring in several places on our front, but the pressure has in general not been such as to prevent the surgeon at the clearing station from performing abdominal section in all desirable cases When advance becomes more rapid conditions will change clearing stations will not be so close to the firing line, a longer time will elapse before the patients reach the hospital, while the pressure of work will diminish the time which can be devoted to each case We may be sure that the utmost will be done to remedy these drawbacks, but clearly the statistics of a casualty clearing station in a fixed position and not overworked must compare favourably with another which is always on the move and almost overwhelmed with the number of urgent cases The results obtained at the base hospital will vary, but in a different way the base hospital receives those cases which have survived the shock of the injury and after elimination of all the more severe cases, for these will be already dead

A perusal of the papers referred to leads to certain provisional conclusions In the first place, it is clear that all abdominal cases, unless obviously moribund, should receive operative treatment, and this at the earliest possible moment after injury, provided that extreme shock is not present Performance of abdominal section during severe shock can only serve to impair the little chance of life remaining to a wounded man Within half an hour warmth usually removes much of the shock in all but the most severe cases, and the abdominal section can then be undertaken Secondly, the operation itself must be performed with the utmost despatch, and the abdominal contents not brought out of the wound more than absolutely necessary Large incisions are therefore indicated The less the bowel is manipulated the better, but examination for perforations must be thorough, omitting no part of the abdominal contents where a wound is likely to be present The recorded experience shows further that abdominal sections can be done when many of the arrangements provided in a civilian hospital are absent It will, we think, still be possible, therefore, in the future, when the casualty clearing station is constantly on the move, for the abdomen to be opened whenever there is a clear hope of saving life by rapid operation In this connexion the use of motor ambulances has helped by shortening greatly the time intervening between the infliction of the wound and the arrival of the patient in hospital We have good reason to be proud of the abdominal surgery done in the casualty clearing stations, and feel assured that the work will be equally well done under the altering conditions

---

THE Medical Research Committee understand that, owing to unavoidable delay at the printing offices, copies of the report upon soldiers returned as cases of "Disordered Action of the Heart" (D A H) or "Valvular Disease of the Heart" (V D H) have not been readily obtainable from H.M Stationery Office Copies are now, however, obtainable through any bookseller from H M Stationery Office, Kingsway, W C 2, at the price of 1*s*

THE ADMISSION OF DEAF CANDIDATES TO THE C M B EXAMINATION —At a recent meeting of the Central Midwives Board a letter was considered from the lady superintendent of the Plaistow Maternity Charity inquiring whether a woman who was quite deaf, but was capable of understanding conversation by means of lip reading, was eligible for admission to the Board's examination The Board directed that the lady superintendent of the Plaistow Maternity Charity be informed that the woman about whom she inquired could not be admitted to the examination

Annotations.

"Ne quid nimis."

THE NATIONAL FOOD-SUPPLY

ACCORDING to the report of the Food Committee of the Royal Society, the consumption of bread in pre war times by the population of the United Kingdom was 5¼ lb per head per week The Devonport allowance of 4 lb represents a reduction of nearly 25 per cent upon our previous habit The reduction of 1–1¼ lb of bread per head per week asked for by Lord Devonport should make no excessive demand upon the national self control. We must, however, remember that physiology teaches that a further reduction in the national bread consumption will be dangerous, and the Government must strain every nerve to ensure that the bread supply, *including all cereals*, is kept up to three fourths of its pre war value The voluntary ration of bread and meat officially recommended to the nation by the Ministry of Food Control has now stood the test of ten weeks' trial, and the possibilities of the Devonport figures are generally recognised If these figures—4 lb bread and 2½ lb of meat per head per week—are taken to represent distribution figures for the whole mixed population of men, women, and children, workers and non workers counting alike as heads of the population, no apprehension need be felt as to keeping up the man power of the nation, but to limit the worker to the 4 lb bread ration must imperil his value. The German experience proves that some time may elapse before this happens, but the risk is one that should be avoided Bread, by which all cereals as food is implied, is the worker's food which nothing can replace The economy of bread is necessary by worker and non worker alike in so far as our customary waste of bread must cease It is imperative on all the sedentary classes in this country to get as far below the bread ration of the Ministry of Food Control as possible, for in this way the expiration of time at which the worker can return to the full bread ration will be assisted The consumption of other cereals than wheat by those who can dispense with them is no true national economy It should be, and probably is the intention of the Government to make some statement on this vitally important matter to the public as soon as an accurate forecast can be arrived at as to the amount of cereals we have in hand The country would also like to learn the views of the Royal Society, expressed through their Food Committee, for an authoritative statement would be very useful Lord Devonport's statement in the House of Lords on Wednesday is satisfactory as indicating that the term of privation which should *now* begin will not last until the period of danger for our manhood efficiency

KORSAKOW'S SYNDROME

IN another column we publish a communication by Dr Hildred Carlill, attached as neurologist to the Royal Naval Hospital at Haslar, on a case of Korsakow's psychosis in association with malaria, which draws attention to a curious and not yet fully understood condition Mental symptoms associated with peripheral neuritis were often recorded by clinical investigators, notably by Dr Allen Starr, of New York before Korsakow, in 1887, described a syndrome subsequently called by his name on the suggestion of the late Professor Jolly, of Berlin Korsakow's own title for it was "cerebropathia psychica toxæmica"—a cumbersome and not very informative term. It indicated, however, the toxic nature of the condition, which, as first described, was supposed to be characteristic of disturbance of the central nervous system of alcoholic origin, linked, in fact, to an actual and obvious peripheral neuritis Hence it has been regarded by some as the expression, clinically, of a "central neuritis," and this, pathologically speaking, is probably not incorrect Many cases have since been reported of Korsakow's syndrome apart from alcohol, and, indeed, apart from any evidence of polyneuritis Oppenheim in one case could find no other cause for the symptoms than a continued use of pyramidon. Further, in not a few cases of alcoholism the mental picture is not comparable in any way to that of Korsakow's "polyneuritic psychosis." Dr Carlill mentions its occurrence in typhoid fever, diabetes, arsenical poisoning, and malaria, almost any toxic or toxi infective state may be supposed, in the presence of certain at present unknown factors, to bring it on As the type of psychosis is, as a rule, peculiarly definite and clear cut, its appearance in the course of widely differing toxæmias is one of the most interesting features of the condition. The megalomania of dementia paralytica is not more precise than the amnesia, paramnesia, and confabulation of Korsakow's symptom complex. In the foreground of the clinical picture is the patient's Unmerkfähigkeit—his incapacity for retaining recent impressions His retention of memories of recent events is incredibly fleeting in a minute or less, sometimes, they have vanished Arising in a sense from this, and no less characteristic, is the patient's confabulation or romancing, and he is often curiously euphoric or good humoured in relating his fanciful tales Hence, also, his illusions of memory and illusions of recognition—so called paramnesia He will believe that he has been out for a walk when he has never left his bed, and will proceed to describe with charming verisimilitude whom he met and what he saw during his constitutional It is obvious, further, that another feature of his mental state is suggestibility, not only does he invent himself, but he believes the most improbable stories foisted on him by the observer His judgment is badly at fault and his critical faculty in abeyance Disorientation and confusion of recent and remote events, and absurd attempts to fill memory gaps and hiatuses, are well illustrated in the case recorded by Dr Carlill It has already been observed that polyneuritis is a frequent but not an integral part of the syndrome Persistently absent Achillis jerks may well represent an old neuritis, were they the expression of a recent neuritis probably other symptoms would be present with them, but these Dr Carlill on repeated examination has failed to discover Hence, the case is of interest also in suggesting either that the mental state has outlasted the neuritis or that it has occurred separately When the clinician is faced with a well defined and circumscribed mental syndrome in the course of an essentially diffuse and unsystematised disease such as a general toxæmia he is justified in asking whether he is dealing with a specific action of the toxin on a certain part or parts of the cerebral cortex. The underlying pathological basis of general paralysis is a diffuse and irregularly massed meningo encephalitis, yet the expansive ideas of the general paralytic are *sui generis* Similarly paramnesia and confabulation form a symptom complex of sufficient definiteness to be readily recognisable, and they occur typically in the course of alcoholic invasion of the nervous system, diffused throughout as we know that invasion must be It can be no mere guess to suppose affinities between certain toxins and certain cerebral layers or groups of cells differing in physical properties, at the least we are compelled to imagine specific interactions between toxins and the chemical activities underlying the function of neuronic systems We may adopt Pick's view and regard the cortex as a mosaic anatomically and physiologically, and patiently dissect from mental symptomatology such separable groups of symptoms as, occurring in the same form and under analogous pathological influences, may lead us to assume that certain neurons are more vulnerable than others, and that their impairment expresses itself clinically always in the same fashion Disorder—perhaps associational—of these neurons gives a clinical picture as definite as that produced by disorder of any of the projection systems, which all recognise and on the definiteness of which the study of neurology is based Assent to the contention that the cerebral mechanism functions as a whole is no reason for ignoring evidence which may afford an insight into the ordered working of its component parts

A NEW ROMAN OCULIST S SEAL

RENEWED interest has recently been taken in the oculist seals of the ancient Roman specialists and we have again to record the discovery of a new signet This was found near Cologne in 1888, but was immediately lost, and only quite recently came to light again Its owner's name, which, as usual, appears four times on the stamp, was Tiberius Julius Jasonis, and the nomina suggest that the seal dates from early imperial times The text is as follows "Tib Juli Jasonis herodes' (euodes) "ad Aspritudines et Cicatrices et cœnum Diaglaucium ad Impetum Secundum in v(eteribus?) c(oti) bur ad Aspritudines et cicatrices to (tollendas) Aliso ad Impetum et quaecunque desi " The incomplete final letters suggest, perhaps, *desicco* or *desino* The first remedy, Euodes, merely means perfume and has been found upon only a few of these seals Of what its ingredients consisted we have no knowledge It occurs upon the seal found at Tranent, in Scotland, and described by Sir J Simpson in the *Monthly Journal of Medical Science* for 1851 The reading upon that relic contains the practically identical sentence, "Euodes ad cicatrices et aspritudines" Its occurrence upon these seals, usually without advising its mixture with any other collyrium, tends to show that it possessed some medicinal properties It is also so advised upon a seal found at Ratisbon Euodes is stated upon a seal, which before the war was in the Lille Museum, to be a cure for genas retortas, words that are a philological crux According to a signet found at Bourges it was to be mixed with opobalsamatum, and here again as contra aspritudines—i e , the palpebral granulations of ophthalmia The cicatrices referred to may be either those of the transparent cornea, an affection which Galen describes thus—"Cicatrix appellatur (exulceratio totas membranas dividens) ubi nigro oculi exalto ulcere membrane crassities supervenit, et color albior apparet", or they may be those of the eyelids or eye sockets, as one seal mentions genarum cicatrices, with which may be compared Ovid s expression—exspoliat que genas oculis Celsus advises various collyria according to whether the cicatrices were cavæ or crassæ For the first case he prescribed Sphaerion, whose value he says was recognised by Asclepius himself Diaglaucium is seldom mentioned upon oculist stamps, and it is uncertain what it was—probably poppy juice Impetum designates the violence of the primal attack of ophthalmia before appearance of the mucous secretion Secundum is a word like the phrase post impetum given upon many seals, it signifies the period when the first severe effects were declining The lacuna in the text for which (c)oti bur is suggested by the first editor of this seal is not easily filled up Also the meaning of the word, or part of a word, Aliso is at present obscure

A POSSIBLE DRAWBACK OF HIGH-TITRE ANTITOXIC SERUM

WHATEVER may be the exact chemical nature of antitoxin, there is no doubt that it is intimately bound to the globulin molecules of the serum which contains it The foreign protein of the antitoxic serums injected into the human patient for the treatment of tetanus and diphtheria is rapidly destroyed in the body, and the more quickly the smaller the quantity injected The attached antitoxin is probably destroyed at the same time, and the question therefore arises whether it is advisable to aim at using small quantities of serum as is done in the modern high titre brands In the *Wien klin Wochenschr* (1916, p 37), T Hamburger called attention to cases of tetanus and diphtheria which did well until the fifth or seventh day of treatment and then suddenly took a turn for the worse, ascribing the occurrence to the destruction by that time of the horse protein, and with it of the antitoxin He suggested the advisability of using a larger quantity of lower titre serum or of adding a large amount of normal horse serum at the moment of injecting Professor Spronck, director of the Pathological Institute at Utrecht (ibid , 1917, p 332), has followed up the question further, confirming Hamburger s suggestion by actual experiment Using antitetanus serum with the mouse as a test object, Spronck found that the blood serum of a goat which received 40 units contained in 40 c c of serum was more antitoxic ten days after the injection than the serum of a goat which had received twice the number of units in half the amount of excipient The goat apparently destroyed 14 c c. of horse serum, and with it the attached antitoxin, in ten days Further experiments confirmed the result Spronck concludes that the views of Hamburger are correct and that it is preferable to use low titre antitoxic serum in tetanus While there may be general agreement with this conclusion in theory, in military practice it would scarcely be feasible For prophylaxis in bulk, at the front, the small quantity—3 to 4 c.c.—of serum of moderate titre now used has great practical advantages and appears to be efficient Large doses of low titre serum, besides troublesome to give, would add to the inconvenience and pain of the wounded For therapeutic use, whether intrathecal or intravenous, the highest titre available is required A further point in connexion with the use of alien serum is of some theoretical interest When prophylactic doses are administered at weekly intervals, the antibody formation against the alien serum is much enhanced, with the result that a progressively increasing destruction of antitoxin occurs, and the protection conferred lasts a shorter and shorter time at each injection There is much still to be learned in the administration of antitoxin

SNAPPING HIP

IN the year 1859 Perrin showed the members of the Parisian Surgical Society a case in which he diagnosed recurrent dislocation of the right hip joint in a man aged 22 who had injured the joint 12 years previously This dislocation could be produced by the patient at will by forcible adduction of the right leg, and was accompanied by a loud snapping sound and a visible jerk, reduction of the dislocation took place spontaneously Thus Perrin, but other members of the society held other views A committee to investigate the matter was appointed and reported to the effect that no dislocation took place, and referred the snapping sound to a movement of muscle tissue over the great trochanter Chassaignac, one of the members of the committee, specified the tensor fasciæ latæ as the muscle here concerned, while Morel Lavallee, another of the members, specified the anterior fibres of the glutæus maximus No further instance of the condition appears to have been recorded until 1900, when Wertheim Salomonsen described two examples as "hysterical deformity of the hip with scoliosis" The patients, a man and a girl, seem to have had each a single "dislocation" of the hip and to have recovered from it suddenly with a loud snapping sound Wertheim Salomonsen diagnosed a "physiological dislocation of the hip," rejecting the view (as Perrin had done) that the condition was due to tension of fibres of the glutæus maximus pressing the great trochanter out of place In 1905 Ferraton described in detail a similar case, under the name "hanche a ressort," or "spring hip," in which the snapping was audible, visible, and palpable In 1911 Heuilly was able to collect 57 cases of snapping hip, or Perrin Ferraton's disease, from the literature It appears, however, that not all the instances of snapping hip are as straightforward as those described above Dr G Kapsenberg proposes[1] to distinguish two classes of the disease, the typical and the atypical In the typical cases the cause of the snap lies at the level of the great trochanter, 'something' slips over this bony prominence and this "something" consists, behind, of fibres of the glutæus maximus, in front, of fibres of the tensor fasciæ latæ, and in its middle part of the converging descending fibrous cristo femoral tract which forms the ilio tibial band The whole is called the "hip deltoid' by Dr Kapsenberg, and is compared to the deltoid muscle of the shoulder joint The distinction of the cristo femoral (Zur Verth) or fascio gluteal (Heuilly) tract from the ilio tibial band is described as functional rather than anatomical In some people the typical snapping of the hip can be produced at will, particularly if the glutæus maximus is kept out of action, the cristo femoral band then slipping forwards in front of the great trochanter harmlessly and without pain But in other instances the snapping is produced involuntarily, and is both disabling and painful, this state of affairs is promoted by any morbid process about the hip that either shortens the cristo femoral tract and so increases its tension, or weakens the glutæus maximus muscle, or increases the prominence of the great trochanter As for the atypical cases of snapping hip, these are rarer, and Dr Kapsenberg defines them as those in which the snap is not produced at the level of the great trochanter but somewhere else He thinks it unlikely that a subluxation of the hip joint accounts for any of the instances, and gives details of a case of his own in which the snap was produced near the anterior superior iliac spine Under local anæsthesia the tissues were dissected in this region, and with the coöperation of the patient it was proved that the snapping band of tissue was a tendinous part of the ilio psoas muscle, in all probability the so called third head of it that springs from the anterior inferior iliac spine and passes obliquely across the head of the femur to gain its insertion into the lesser trochanter The head of the femur at this point was thought to be abnormally prominent, though no definite bony outgrowth was made out, and when the patient flexed the hip the overlying tendinous part of the ilio psoas muscle slipped from it sideways and outwards with a loud and palpable snap Conversely, when the patient once more extended the flexed leg, the sharp edge of the head of the femur held up the tendinous band under increasing tension until, as a smoother part of the bone came to underlie the band, it slipped back medial wards with a violent snap and shock Dr Kapsenberg divided this band, the wound was sewn up and healed by first intention, and the patient's hip no longer could be made to snap

THE Croonian Lecture of the Royal Society will be delivered on May 3rd by Dr Thomas Lewis, the subject being "The Excitation Wave in the Heart"

THE CONTROL OF VENEREAL DISEASES

Council Schemes

THE draft scheme for the *City of Bristol* recently submitted to the Local Government Board provides for the clinical work of the venereal treatment centres to be undertaken jointly by the Bristol Royal Infirmary and the Bristol General Hospital and for the pathological work to be carried out at the laboratory of the University of Bristol under the professor of pathology

Dr F H Morison county medical officer of health, has submitted to the *Cumberland County Council* a suggested scheme for the diagnosis and treatment of venereal diseases in the county In order to obtain some idea of their prevalence Dr Morison sent a circular letter to each medical practitioner in the county asking him how many cases of venereal diseases he treated in a year He says

> A large majority were good enough to reply to my letter but several did not and so even these figures are incomplete. The figures I obtained are as follows —Number of cases of syphilis 479; gonorrhœa 637 soft chancre, 131 total 1147 It is generally agreed that in any community gonorrhœa is at least three times as prevalent as syphilis but it will be noted in the figures given for this county that there are only 68 more cases in an average year There can be no doubt that a large number of cases of gonorrhœa, and many cases of syphilis as well in poor persons go to chemists herbalists and quacks for treatment I think it is no exaggeration to say that 70 per cent of the cases of gonorrhœa go to a quack in the first place

With regard to the provision of laboratory facilities, no laboratory exists in the county where the work could be done except that in connexion with the County Health Department Dr Morison proposes, therefore to ask the Durham University College of Medicine Newcastle on Tyne to give the same facilities as have been offered to the county councils of Northumberland and Durham He hopes to arrange for beds and out-patient centres at Carlisle and Whitehaven, noting that the authorities of Workington Infirmary and of Penrith and Keswick Cottage Hospitals were unable to offer facilities In view of the desirability of having a woman doctor to treat cases in females and believing that at present there is no woman doctor in the county, he suggests the appointment of a woman on the staff of the county medical officer Dr Morison regards the cöoperation of the general practitioner as essential to the success of the scheme and suggests that representatives of all branches of the profession in the county should be asked to attend the committee meetings In his summary of expenditure he allows for the treatment of at least 500 cases of gonorrhœa per annum and fixes the total between £1800 and £2200 for the first year

---

[1] Nederl Tijdschr v Geneeskunde Amsterdam 1916 ii 1849

The scheme submitted by the *County Borough of Bournemouth* for the approval of the Local Government Board contains, amongst others, the following recommendations by Dr A D Edwards the medical officer of health —

Laboratory facilities —That arrangements be made with the Hants county authority for the examination at the Winchester Laboratory of blood specimens by the Wassermann test at a charge of 5s per specimen (*It is estimated that in the first year 200 specimens will be* forwarded from the venereal clinics provided for the Bournemouth authority and 20 specimens from private *medical practitioners in* Bournemouth.) That arrangements be made with the Bournemouth borough bacteriologist for the examination of specimens with a view to the detection of the spirochæte of syphilis and the micro-organism of gonorrhœa at a charge of 3s 6d per specimen and if the number of spirochæte examinations falls below 60 during the year of 4s per spirochæte specimen (It is estimated that in the first year the clinic will require 200 examinations for gonorrhœa, and 100 for syphilis and that medical practitioners in Bournemouth will require the examination of 40 specimens for gonorrhœa and 20 for syphilis) That the *medical officer of health make arrangements for the provision* of apparatus for the collection of specimens, with circular of instructions The estimated expenditure on these recommendations is £146.

Clinics and hospital beds —That arrangements be made with the Royal Victoria and West Hants Hospital and with the Cornelia Hospital Poole for the treatment at clinics of patients from Bournemouth and for the in patient treatment of such of these cases as may require it. (A tentative estimate of the cost incurred by the treatment, except the supply of salvarsan, at the Bournemouth Voluntary Hospitals is £350 and at the Poole Voluntary Hospital £70)

Extra clinic consultations —That arrangements be made with the senior medical officer of the Bournemouth Hospital venereal clinic for attendance at consultations with medical practitioners elsewhere than at the clinic, at a charge of £1 per consultation. (During the first year ten such cases are estimated for)

The report recommends further That infants—if breast-fed, accompanied by their mothers—suffering from ophthalmia neonatorum should be admitted into the sanitary hospital, and that the medical officer of health, in addition to his other duties, should give addresses on venereal diseases to clergymen, pharmacists, and midwives

Enlightenment Campaign

A conference of citizens representing the various interests —municipal, industrial, educational, social, and religious—in the metropolitan borough of Southwark has been convened by the Mayor of Southwark at the Town hall, Walworth road, London, S E, on Friday, May 4th, at 5 P M The chairman and honorary secretaries of the National Council for Combating Venereal Diseases will outline the work of the National Council and suggest methods for an effective educational campaign

Unqualified Treatment and the Central Midwives Board

At a recent meeting of the Central Midwives Board a letter was considered from the honorary secretary of the Leicester and Leicestershire Midwives Association urging the immediate introduction of legislation for the purpose of rendering it a penal offence for any person other than a qualified medical practitioner to undertake the treatment of venereal diseases The Board decided—

That, in view of the grave national dangers arising from the neglect or the improper treatment of venereal diseases the Central Midwives Board considers that legislation should be introduced with the least possible delay for the purpose of rendering it a penal offence for any person other than a registered medical practitioner to undertake the treatment of venereal diseases and directed that this decision should be communicated to the National Council for Combating Venereal Diseases

---

LITERARY INTELLIGENCE —Messrs Butterworth & Co (India), Limited announce the forthcoming publication of a monograph on 'The Treatment of Kala-azar," by Dr U Brahmachari, lecturer on medicine at Campbell Medical School

---

COLLOSOL COCAINE

THE successful outcome of the experiments leading to the production of colloidal quinine, morphine, and cocaine was foreshadowed by THE LANCET, and we are now able to state that a collosol of cocaine has been prepared at the Crookes Laboratories, where the idea was conceived of obtaining the alkaloids in colloidal form isomorphic with the colloidal protein of the body A quinine collosol is also, we understand, prepared.

Samples of collosol cocaine have been submitted to Professor W J Simpson, professor of hygiene, King's College, London, Professor R Tanner Hewlett professor of bacteriology in the University of London, and to Dr John Eyre, director of the Clinical Bacteriological Departments, Guy's Hospital, whose reports on the tests made with the object of testing the toxic and anæsthetic properties of this drug are as follows —

University of London King's College, Strand W C.
March 23rd 1917

TESTS OF TOXICITY

1 per cent Collosol Cocaine	*1 per cent. Cocaine Hydrochloride.*
I Rabbit No 4 —Weight, 3270 grammes 0 26 c.c. injected intravenously No effect. (March 13th)	I Rabbit No 3 —Weight, 2070 grammes. 0 20 c.c. injected intravenously No effect (March 13th.)
II Rabbit No 4 —0·75 c.c. injected intravenously No effect (March 13th)	*II Rabbit No 3* —0·5 c.c injected intravenously No effect. (March 13th.)
III Rabbit No 4 —5 c.c. injected intravenously No effect. *(March 15th)*	III Rabbit No 3 —3 c.c. injected intravenously Immediately after injection the animal collapsed and became insensible 5 minutes later convulsive twitchings, eyes insensitive. 10 minutes recovering but weak on hind legs and eyes now sensitive 15 minutes practically recovered. (March 15th.)
IV Rabbit No 3 —3 c.c. injected intravenously No effect. (March 16th.)	IV Rabbit No 4 —5 c c. intravenously Collapsed immediately after injection, with slight twitching and died almost at once. (March 16th.)
V Rabbit No 6 —Weight, 2770 grammes 5 c.c. injected intravenously *No effect*	V Rabbit No 3.—3 c.c. injected intravenously Immediately collapsed and died. (March 19th)
VI. Rabbit No 6 —10 c.c. injected intravenously No effect. (March 19th)	VI Rabbit No 5 —Weight, 2750 grammes. 3 5 c c. injected intravenously Immediately after injection was convulsed and died almost at once (March 19th.)

From these tests of toxicity we find that about 3 c.c. of a 1 per cent solution of ordinary cocaine hydrochloride (equivalent to about ½ grain) is a fatal dose for a rabbit of 2000-3000 grammes weight, injected intravenously

As regards the collosol cocaine, 10 c.c. of the 1 per cent. preparation (equivalent to about 1·6 grains) produced no toxic effect whatever

W J SIMPSON
R. T HEWLETT

Guy's Hospital (Bacteriological Department),
April 21st, 1917

REPORT ON SPECIMEN OF COLLOSOL COCAINÆ 1 PER CENT RECEIVED FROM MESSRS CROOKES LABORATORIES

A. *Toxic properties* —A full grown rabbit, weighing 2000 grammes received on March 1st 2 c.c. of collosol cocainæ 1 per cent. intravenously the injection being made at the rate of 1 c.c. per minute. No immediate or remote effects were observed. On March 12th, the same rabbit received 15 c c of the same solution intravenously within ten minutes No immediate or remote effects were observed. Five hours later 3 c c. of the 1 per cent. solution of cocainæ hydrochlor were injected at the rate of 1 c.c per minute Just before the injection of the third c c had been completed the animal was seized with convulsions and died within a minute. Identical results were obtained on two subsequent occasions In my opinion therefore collosol cocainæ can be regarded for all practical purposes as non toxic.

B *Anæsthetic properties* —1 Two drops of collosol cocainæ dropped into the left eye of a rabbit produced mydriasis and complete anæsthesia in three minutes 2. Two drops collosol cocainæ instilled into the left eye of the human subject produced complete anæsthesia and enabled me to remove a foreign *body embedded in* the cornea without pain (I can personally vouch of the completeness of the anæsthesia as the *foreign body* was embedded in my own cornea and I removed it myself in front of the looking-glass) 3. 0·8 c.c. collosol cocainæ injected into the male urethra (a very nervous and sensitive patient) produced complete anæsthesia in five minutes and permitting the passage of a 7 5 mm. urethrascope.

The above three representative examples indicate the nature of evidence which in my opinion, establishes the claim of the Crookes collosol cocainæ that it can be regarded as an efficient local anæsthetic.

JNO EYRE.

It is certainly not a little remarkable that colloidal cocaine can be given exclusively for its anæsthetic effects, and it seems probable that we are in the presence of a remarkable development in therapeutics as we on a previous occasion predicted might occur in connexion with colloidal treatment.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

To be temporary Surgeons: R. E Rampling D Heard T. L P Harries, F M. Mosely A. E. P Parker N Braithwaite.

The following appointments have been notified— Fleet Surgeon: W H Pape to *Pembroke*. Surgeons: C F Willis to *Halcyon*, and E C Holton to *Vivid*. Surgeons (temp) M Neilson to *Leander* R A. Hobbs to *Albion* D W Warren J R S Thompson, and J H B Hogg to *Vivid* R M Barrow and R L. Glass to *Pembroke*, H Waldo and J L. Lamond to *Victory*

ARMY MEDICAL SERVICE

Col J T Fotheringham, C.M.G Canadian A.M.C to be temporary Surgeon-General

Lieut.-Col (temp Col) R R. Sleman relinquishes his temporary rank on vacating the appointment of Assistant Director of Medical Services.

Col. J H Daly is retained on the active list and to be supernumerary

Capt D W Hardy to be Deputy Assistant Director of Medical Services

TERRITORIAL FORCE.

Lieut.-Col W K Clayton to be temporary Colonel whilst an Assistant Director of Medical Services

Lieut.-Col (temp Col) J Young relinquishes his temporary rank on vacating the appointment of Assistant Director of Medical Services

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. R R. Sleman is restored to the establishment.

Capt. (temp Maj) J W Keay to be acting Lieutenant-Colonel whilst commanding a Field Ambulance

A. M Paterson to be temporary Major

Temp Capt Gerald S Samuelson to be temporary Major whilst commanding troops on a Hospital Ship

Capt. R. C Carlyle is seconded for service with the Egyptian Army

Capt. D W Hardy is seconded while holding an appointment as Deputy Assistant Director of Medical Services

Lieut A C Ainsley to be Captain

Temp. Lieut George F B Simpson to be temporary Captain

H T Thomson to be temporary Honorary Captain whilst serving with No 11 Stationary Hospital.

E Harding to be temporary Honorary Captain whilst employed with No 22 General Hospital.

Temp. Capt. F G Crookshank relinquishes his commission

Temp Hon Lieut T A. Loughrey from Canadian A.M.C to be temporary Lieutenant

SPECIAL RESERVE OF OFFICERS

Lieutenants to be Captains: T Crisp, A. L. Giblin, M McG Russell R C B Ramsay, A. L. V Davin W Richards

TERRITORIAL FORCE.

Lieut. Col W K Clayton is seconded whilst holding an appointment of Assistant Director of Medical Services

Capt (acting Lieut -Col) A. A. Hingston reverts to the temporary rank of Major on ceasing to command a Field Ambulance

Lieut. Col. J Young is restored to the establishment

Capt. (temp Lieut. Col) P Moxey relinquishes his temporary rank on ceasing to command a Field Ambulance

Capt. B. G Annis to be acting Major whilst in command of a Field Ambulance

URBAN VITAL STATISTICS

(Week ended April 1 th 1917)

English and Welsh Towns —In the 96 English and Welsh towns with an aggregate civil population estimated at nearly 17 000,000 the annual rate of mortality was 18 5 against 18·0 and 17 3 per 1000 in the two preceding weeks In London with a population exceeding 4 000,000 persons the death rate was 19 5, or 2·6 per 1000 above that recorded in the previous week among the remaining towns the rates ranged from 7·0 in Edmonton 8 2 in Grimsby and 9·1 in Eastbourne to 28 2 in Dudley and in Southend-on Sea, and 38·6 in Hastings The principal epidemic diseases caused 505 deaths which corresponded to an annual rate of 1·6 per 1000 and included 320 from measles 66 from whooping-cough, 51 from infantile diarrhœa 45 from diphtheria, 13 from enteric fever and 11 from scarlet fever The deaths from measles showed a further increase compared with the numbers in the 11 preceding weeks, and caused the highest annual death rates of 3·6 in West Ham and in Sunderland 5·2 in South Shields 5·9 in Bolton and 7 3 in Dudley The 722 cases of scarlet fever and the 1317 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 33 below and 20 above the numbers at the end of the preceding week Of the 6010 deaths from all causes in the 96 towns 167 resulted from violence. The causes of 67 of the total deaths were uncertified and included 10 in Liverpool 8 in Birmingham and 5 in Sheffield

Scotch Towns —In the 16 largest Scotch towns with an aggregate population estimated at nearly 2,500 000 persons the annual death rate was equal to 19 1 against 17·9 and 16·9 per 1000 in the two preceding weeks The 410 deaths in Glasgow corresponded to an annual rate of 19 2 per 1000 and included 27 from measles 22 from whooping-cough 7 from infantile diarrhœa, and 2 from diphtheria. The 141 deaths in Edinburgh were equal to a rate of 22·2 per 1000 and included 22 from measles 18 from whooping-cough and 1 from infantile diarrhœa.

Irish Towns —The 225 deaths in Dublin were equal to a rate of 25 8 or 2 1 per 1000 above that recorded in the previous week, and included 15 from measles 2 from infantile diarrhœa, and 1 from whooping-cough The 173 deaths in Belfast corresponded to an annual rate of 22 6 per 1000 and included 4 each from enteric fever and measles and 3 each from whooping-cough and infantile diarrhœa.

"SOLDIER'S HEART"

To the Editor of THE LANCET

SIR,—As medical adviser to a large insurance company a considerable number of cases were referred to me recently in connexion with the short-term endowment policies for the purpose of the War Loan Among them one group specially impressed me in relation to the subject of "soldier's heart" recently discussed in your columns

I saw several young men, some looking jaded and worn, others robust and well, who all alike said they had been discharged from the Army as unfit for service for valvular disease of the heart, some showed me their certificate to that effect On my examination the heart yielded no abnormal physical signs It was of the usual size its apex in the proper place, its action regular, and its sounds normal There were no murmurs and no cardiac symptoms The heart was therefore presumably healthy It was, at any rate, certain that there was no valvular disease The men when at the front, I ascertained, had some cardiac symptoms—viz., shortness of breath, palpitation, and even pain on exertion—i.e, signs of cardiac overstrain They were therefore rightly put upon the sick list. I presume there must have been murmurs also upon which the diagnosis of valvular disease must have been made

The cardiac murmurs which are associated with nervous excitement and with dilatation of the heart do not seem to be as familiar as they should be to those who are responsible for these certificates for though the cases I speak of came in a group several others have fallen under my observation in private practice, and I have for some time had it in mind again to draw attention to the subject These functional murmurs, as they are usually called, are almost without exception systolic, and may be heard at the base or apex, or widely over the whole præcordium. Of the base murmurs it is unnecessary to refer to those at the left or pulmonary base, associated with anæmia, especially as they are hardly ever met with in young men A more important murmur but one rarely referred to, and, I think, not generally recognised, is that which, systolic as usual, occurs over the aortic base and above. It is more frequently met with under those very conditions which these "soldier's" cases would present—viz., nervous excitement where the results of the examination and the decision based upon them are important, and arouse anxiety in the candidate In ordinary times this murmur is most often met with in candidates for insurance, where marriage, it may be or a valuable appointment hangs upon the verdict This murmur is often quite loud, audible at the right base and for a short distance above, and it may be almost musical. It is not unlike the murmur of slight organic disease but it is transitory, disappearing, it may be, in a few minutes when the excitement passes off, and it is easily reproduced if the excitement returns

Besides these murmurs at the base, transitory murmurs may be heard at the apex or over the body of the heart. These have been called dilatation murmurs—not a good name as mixing up facts and interpretation, but justifiable perhaps in this instance as the murmurs vary with the dilatation and come and go with it. Though systolic in time they are not propagated as they should be if these were due to regurgitation through the mitral or tricuspid valves On the left side they are limited to the præcordial area and are not heard in the axilla or behind. Where dilatation of the heart is extreme they may be propagated just as the murmurs due to organic disease both on the right and left side, and these no doubt are truly regurgitant but it is not in these cases that the diagnosis is difficult for the evidence of extreme dilatation is obvious When the heart is weak, as in convalescence from long illness these murmurs may be easily produced by a little over exertion and their association with dilatation be easily demonstrated

The diagnosis of valvular disease of the heart is a serious matter for the subject of it Wrongly made it may unfairly ruin a promising career in the Army or in some other profession where a certificate of health is required while it will of course, strongly prejudice the prospects of life insurance Worst of all, it may partly by the alarm it may excite, and *partly owing to the treatment* which such a diagnosis is thought to involve, convert the unhappy victim into a cardiac hypochondriac, and make him a misery to himself and all about him I recall the case of a young man who presented himself for examination for an insurance on his life prior to his marriage *The doctor looked gravely* at him and said, ' Young man, *walk* through life " He did not *walk through life*, but ran at a racing speed Yet he lived till a good age, and never had a cardiac sign or symptom Fortunately, the man had too busy a life to act on the suggestion or to dwell on it Otherwise it might have been disastrous

If *the* existence and frequency of these murmurs be kept in mind the diagnosis is, as a rule, not difficult Mistakes can be avoided by a little more knowledge and caution The knowledge would suggest caution, and the caution would be justified by the disappearance of the murmurs and the proof that the *suggested diagnosis was wrong*

I am, Sir, yours faithfully,

Wimpole-street, W, April 21st, 1917 SAMUEL WEST

"MILITARY CARDITIS"

To the Editor of THE LANCET

Sir,—*May I suggest* "*military carditis*" *as* a useful term for the soldier s cardiac effort syndrome of which so much has been heard recently? We have the authoritative example of Thomas Watson for such a comprehensive term when dealing with a problem that is not easily defined, and as a former pupil of Dr *Frederick Roberts I think* there is much to be said for the emphasis he used to lay upon what he called "cardiac apparatus" when discussing problems of the heart In an organ like the heart where the three parts—endo myo-, and peri cardium—are so intimately associated it is difficult to draw a hard and fast line between disease of the one and the others, in fact, in many cases it cannot be done

So far attention has been devoted almost entirely in "military carditis" to the myocardium, apparently because the peri and endo cardia do not show any gross lesions, but neither does the myocardium in many cases I have drawn attention elsewhere to the importance of the peri cardium and its fluid, pointing out that that fluid exists *normally under a negative pressure, whereby the fluid is kept* at an equal thickness all over the surface of the heart I have pointed out also that most likely the movements of this peculiarly circumstanced fluid have much to do with the sounds of the heart, a contention that is supported by my rubber balloon experiments The opinion I have formed after examining many hundreds of men before the furnaces as well *as boys before and after running*, *is* that the increased cardiac dullness is due to an increase of pericardial fluid which is of such physiological importance in connexion with the running of the accelerated heart Experiments also bear out this statement, for the pericardia of rabbits shot *standing contain less* fluid than the pericardia of those shot when driven out by ferrets—i e, under stress and strain Another interesting fact in this connexion is that the effect of killing cats by chloroform is to cause an increase of peri cardial fluid and a sudden variation of the intrapericardial pressure

Does shell shock produce such a sudden variation of the intrapericardial pressure? and does it thereby cause a dis turbance of the regular wave movements of the fluid which are to a great *extent responsible for* the sounds of the heart? Dr Lewis, who is quoted as an authority on electro cardiography, states that the curves are due to impulses which have travelled the auriculo ventricular bundle, although similar curves are obtainable from the lower order of animals in which there are no such bundles! The fact that throughout the vertebrate series we find pericardia and pericardial fluids is *evidence of their great* importance, and that the latter have much to do by means of their electrical resistance with the causation of the so-called *electro-cardiograms*

As a result of my experiments I have devised a double chested stethoscope which I call the "Cardioscope" whereby I find that in normal hearts the sounds conducted to each ear separately are equal, whereas in abnormal states the sounds are *unequal By this* instrument one hears the "murmurs" resolved into other sounds

I am, Sir, yours faithfully,

Swansea, April 14th 1917 G ARBOUR STEPHENS

THE TECHNIQUE OF LUMBAR PUNCTURE

To the Editor of THE LANCET

Sir —Surgeon F A Williamson's letter in your issue of April 21st refers, as you remark, to a real difficulty occa sionally experienced in the *technique of lumbar puncture* and one to which he does well to draw attention The failure *of a considerable collection* of cerebro spinal fluid to flow freely until the needle is manipulated whilst *in situ* may be due to the fact that a constituent of the cauda equina temporarily blocks the needle at its orifice or that the needle at first enters only a small loculus of fluid and not the main cisterna *In connexion* with the *first possibility* it may be noted that if the lumbar cisterna is distended by fluid there would be a greater tendency for a nerve root to be pressed against the orifice of the needle than if the normal conditions obtained. In connexion with the second possibility, it must be remembered that the pia arachnoid system is not a simple cavity but a *series of small and large cavities separated* by *trabeculæ*. The free intercommunication in health of the loculi so formed is no doubt interfered with in disease by the added factor of plastic lymph deposit Whatever the cause may be, the moral, as your correspondent points out, is not to be content with a restricted flow in any case, and especially not to be content with this result in a case suspected on clinical *grounds to be one of* cerebro spinal fever, *until the needle is* pushed a little farther in or is slowly withdrawn a little or is tested as to its patency by passage of the trocar or stylet I use the term ' restricted flow" rather than "at a normal rate" in such a case because I am always more suspicions that I am *dealing* with an instance of the difficulty to which your correspondent refers when the fluid flows at *less* than the normal rate *I think many practitioners under* estimate the initial rapidity of the normal rate of flow immediately after the puncture is made

It may not be out of place to refer to one or two other difficulties that not infrequently present themselves in con nexion with lumbar *puncture One of these* again has to do with restricted flow of the fluid. Operators sometimes use a long needle for a small patient, and do not notice that the needle is pointing upwards its delivery end being well above the level of any part of the cerebro spinal system This difference of levels may have been increased by raising the hips well on to the edge of the bed for convenience of the procedure, thus leaving the child's trunk and head in the trough of the bed Should the cerebro-spinal pressure not be much, or at all, raised, very *little fluid may flow* until the patient s hips are rolled over towards the needle, the delivery end of which is thus brought to a much *lower level* Thi point in technique becomes important when it has been decided to drain a highly purulent exudate as *completely* a possible

The admixture of blood with the cerebro-spinal fluid con stitutes another difficulty in the technique, as it prevent accurate chemical and histological investigations If this i seen to occur the first few drops of *fluid should* be received into a separate vessel (indeed this is always a sound thing to do), and the needle should be slowly withdrawn a little because it is very likely that the *blood* is contributed by th venous plexus lying on the anterior wall of the canal I the *blood is still present*, and it is not obvious from th naked eye examination that the fluid is also purulent—i which case the histological and chemical examinatio becomes of no great differential value—the needle shoul be withdrawn and a fresh puncture *should* be made at different space

Finally, a word may be added in regard to so-called "dr punctures ' If the points in manipulation referred to abov are *observed* it may almost certainly be concluded that th *meaning of a dry puncture* is that the needle has not entere the pia arachnoid space at all

I am Sir yours faithfully,

Harley street W April 22nd 1917 THOMAS J HORDER.

THE AFTER-TREATMENT OF INFECTE HÆMOTHORAX.

To the Editor of THE LANCET

Sir —Since one of the chief dangers of an infected hæm thorax is the secondary infection which almost invariabl occurs after resection and drainage, any method of treatme which will lessen or prevent this will prove of the utmost importance and value

The results of the Carrel-Dakin method have been most striking and shown by —1. The uninterrupted improvement in the general condition of the patient after resection and the rapid settling of the temperature 2. The very rapid obliteration of the cavity 3 The small quantity and inoffensive nature of the discharge. 4 The firm primary union of the sutured portions of the empyema wound.

After resecting and draining in the usual way the Dakin's solution is not at first run into the pleural cavity on account of the risk of breaking down loose adhesions, but the dressings are kept constantly moist by means of irrigation every two hours with a few ounces of the solution The procedure here is to use a Carrel tube in the form of a horseshoe with multiple small perforations. The open ends are connected with the tube leading to the reservoir by a two-way glass connexion. The horseshoe is kept in position by being placed under the safety pin of the drainage-tube and by being attached to the chest higher up The surrounding skin may be protected with sterile vaseline but in practice this is not essential, since the hypochlorite rapidly loses its tendency to irritate after contact with the discharge from the empyema After ten days or a fortnight a Carrel tube with few terminal perforations may be inserted into the pleural cavity alongside the drainage-tube and irrigation every two hours with a few ounces of *half strength* Dakin Daufresne solution carried out

After an extended experience of septic hæmothorax and the deleterious effects of the secondary infection after resection we have been firmly convinced of the value of the above method in lessening or almost preventing this important complication. I am Sir yours faithfully

C DEAN M B Oxon

Millicent Sutherland Ambulance, B.E.F., April 17th, 1917

THE CLOSURE OF COLOTOMY OPENINGS

To the Editor of THE LANCET

SIR,—Had Mr P Lockhart-Mummery, in his letter to THE LANCET of April 7th, confined himself to the subject of his paper I should not have troubled you with a second communication but as he has extended his remarks to the methods of treating cancerous growths of the colon and asks Why are surgeons so shy of primary resections and suture of the colon that they subject their patients to three operations where one would do " and as he goes on to say that this seems an altogether unnecessary procedure " his attitude towards a subject of which he professes to be a master demands attention

If he will turn to the transactions of the Surgical Section of the International Congress of Medicine held in London in 1913 he will find in the report of Professor Bastianelli and the subsequent discussion on the treatment of cancer of the colon the answer he requires [1] As this report in full may not be accessible to some of your readers I may say, briefly, that one of the most serious bars to the success of primary resection of the colon is the presence of hard fæcal masses above the growth and that this handicap can be removed by a preliminary proximal colostomy followed by washing out the diseased segment of bowel. By this means we secure a relatively clean field for operation while afterwards the line of union is freed from the irritation of the fæcal stream now diverted Again, intracolic pressure and tension on the suture line from gaseous distension are entirely obviated and rest, so essential to good union of intestinal wounds is secured It is worth while noting that Mr Lockhart-Mummery, in a later paragraph in his letter while advocating his view that the bowel should be made to act daily from the time of the resection unconsciously furnishes reasons for the multiple operation Thus he states that flatus in the bowel is far more dangerous than a little liquid fæces " and, again that the one thing to avoid is the presence in the neighbourhood of the anastomosis of masses of hard fæces

From a long and fairly large experience of resection of the colon with and without actual intestinal obstruction I am firmly convinced that the inclusion of a preliminary colostomy has reduced enormously the death rate of the operation Reverting to the original subject Mr Lockhart-Mummery asserts that the Greig Smith operation is 'liable to leave a weak spot," that 'many patients have to wear a belt " and that ' it may be followed by stricture." My reply is that I have not seen a single instance of any one of these defects, nor do I think any of them should occur if the operation is properly done, and certainly not in the case of young soldiers with well-developed abdominal muscles Possibly some ambiguity as to the essentials of the procedure has arisen from calling it the extraperitoneal method Personally, as I said in my former letter, I do not dread opening the peritoneum. The one factor which makes the operation so much safer than resection of the bowel is that the mesenteric side of the colon with its vascular and nerve-supply is not interfered with.

As to details the most important thing to attend to is to freely mobilise the opening and the adjacent colon When this has been done the involved segment can be lifted out of the abdomen, and with adequate gauze packing it is a matter of little or no consequence whether the peritoneum is or is not, opened. As to stricture following the operation bearing in mind that usually at least one-half of the circumference of the bowel is not involved and that if the sutures are inserted at right angles to the long axis of the colon the lumen is not encroached on and that most preliminary colostomies are placed in the capacious ascending colon, there need be no fear of this developing One word as to the spur This formidable bugbear exists only so long as the colon is anchored to the abdominal parietes. Freely mobilise the involved segment of the bowel and the spur ceases to have any significance and enterotomes any useful application. I am, Sir, yours faithfully

Sheffield April 7th 1917 SINCLAIR WHITE.

READING BY EAR

To the Editor of THE LANCET

SIR,—I notice in your issue of April 14th certain criticisms by Sir Arthur Pearson on the speed attainable in reading ordinary letterpress by ear with the optophone. The speed attained on March 28th was a maximum of three words a minute My estimate of 25 words a minute was based on the fact that the signals remain clear and characteristic at that speed. It is therefore only a matter of practice Three months ago neither I nor anybody else had ever read a line of letterpress by ear The reading of the *Times* blindfold is now a possibility demonstrated beyond doubt or cavil. The instrument is substantially that described in Roy Soc. Proc. A, 90, p 373 —I am, Sir yours faithfully,

E. E FOURNIER D ALBE, D Sc.

Maddox-street W., April 20th, 1917

Obituary.

WILHELM WINTERNITZ

Wilhelm Winternitz, who died, we now learn, on Feb 22nd at the age of 82 years, was emeritus professor of medicine in the University of Vienna and had long earned the title of the "father of scientific hydrotherapy," presiding in this capacity at the last great balneological congress held at Meran before the war From the time of his inaugural dissertation (1865) on "The Rational Basis of Certain Hydrotherapeutic Measures' to the appearance a few days before his death, of "The Water Cure and Natural Immunity ' Winternitz was constantly occupied in research on physical treatment Many of his studies of the action of thermo-mechanical influences on the circulation and metabolism are now classical, as well as the long and bitter feud between himself and Liebermeister with regard to the bath treatment of infectious diseases. His idea of determining a blood flux to particular organs and parts of the body was worked out in great detail long before Bier annexed the word "hyperæmia." Winternitz's belief in his own methods was very great so that he imbued his patients with a like confidence, and he was for nearly half a century one of the busiest consultants in Vienna. But in spite of his great popularity he remained an inquirer and a research student to the last intent on improving the field of medicine which he had so specially made his own

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Capt T W Martin R A M C, attached Royal Scots, received his medical education at Victoria University, Manchester, and qualified in 1912 He was in practice at Hale, Cheshire, before joining the R A.M C

Capt V K Sadler, R A M C was educated at Rossall School and at University College, London and qualified in 1907 After serving as medical officer at Tiverton Infirmary he became a surgeon to the P and O Line Later he joined the R A M C, and went to the front at the beginning of this year

Capt G R Plaister, R A M C, attached York and Lancaster Regiment, was a student at the London Hospital and qualified in 1905 He was in practice at Tottenham, London, before joining up, and went to the front in September, 1915, taking part in the engagements at Loos and on the Somme

Lieut E Evans, R A M C, attached Royal Welsh Fusiliers

Accidentally Killed

Capt J J Weaver, R A M C, was a student at University College, London, and qualified in 1886 He was medical officer of health for the county borough of Southport, and had made several contributions to the medical journals He died at Curragh Camp as the result of a riding accident

Died

Lieut L G Scudamore, R A.M C, was a student at St Thomas's Hospital, London, and qualified in 1891 He was in practice at New Tredegar, Mon, prior to joining the R A.M C in June, 1916, and died in camp in England after a short illness

Capt T McCosh, M C, R A.M C, qualified at Glasgow in 1905 and held a house appointment at the Glasgow Western Infirmary He was in practice at Woodford Green, Essex, previous to joining the R A M C, and had been awarded the Military Cross

Died of Wounds

Lieut J A Gregory, R A M C, was educated at Manchester University and qualified in 1914 He held the appointment of house surgeon at the Evelina Hospital for Children, London, and joined the R A M C in June last

Wounded

Major G J Boyce Canadian A M C

Capt J F Murphy, M C, R A M C, attached Royal Field Artillery

Capt W Parker, R A M C, attached King's Own Scottish Borderers

Capt J S Prentice R A.M C, attached Royal Berks Regiment

Capt J G Brown, R A.M C, attached Royal Irish Rifles

Capt A. Short, New Zealand Medical Corps

Capt A. H Thomas, R A M C

Capt T C Storey, R A.M C

Capt R J Gardiner, Canadian A M C

Capt G R Johnson, C A.M C, attached Canadian Infantry

Capt W G Goudie, R A M C, attached Royal Flying Corps

Capt R A. W Proctor, R A M C, attached Royal Fusiliers

Capt G J Linklater, R A M C

DEATHS AMONG THE SONS OF MEDICAL MEN

The following sons of medical men must be added to our lists of those who have fallen during the war —

Second Lieut R A Patterson, Rifle Brigade, second son of Dr C S Patterson, of Eastbury, Berks

Lieut B Rundle, Australian D A C, youngest son of the late Dr G E Rundle, of Creewood, Sydney, Australia

V E J Bristowe, R A.M C, attached East African Expeditionary Forces, youngest son of the late Dr J S Bristowe, F R S, of London

Capt T W Martin, R A M C, attached Royal Scots, younger son of the late Dr W Y Martin, J P, of Walkden, near Manchester

Capt K J Barrett, Royal Fusiliers, elder son of Lieut Col J W Barrett, C M G, R A M C, of Melbourne, Australia

Capt J J Weaver, R A M C, elder son of the late Dr J Weaver, of Southport

Lieut W D Chepmell, Royal Sussex Regiment, son of Dr C Chepmell

Second Lieut H C Oulton, Leinster Regiment, second son of Dr H W Oulton, of St Stephen's Green, Dublin

FOREIGN DECORATIONS

By the King of the Belgians

Ordre de la Couronne—*Officier* Capt. S R. Douglas, late Indian Medical Service St Mary's Hospital London, Temp Col. Sir A. E. Wright C.B Army Medical Service, St. Mary's Hospital, London. *Chevalier* Temp Lieut E Shaw, R A.M C

By the King of Serbia

Order of the White Eagle 4th Class—Lieut. Col. E T F Birrell, C M G R A.M C Maj M J Cromie, R A.M C

By the Sultan of Egypt

Order of the Nile—*3rd Class* Maj R. G Anderson R.A.M.C, late Assist Adjt. Gen Recruiting Dept. Egyptian Army; Maj W Byam, R A M C late Medical Corps Egyptian Army *4th Class* Capt. E Gibbon R A M C attached Medical Corps, Egyptian Army

THE CENTRAL MEDICAL WAR COMMITTEE AND THE MOBILISATION OF THE MEDICAL PROFESSION

Lord Derby's letter to the medical profession was the subject of discussion at a special joint meeting on Tuesday last of the Central Medical War Committee and the Committee of Reference of the Royal Colleges, when the following resolution was unanimously adopted on the motion of Sir Watson Cheyne, President of the Royal College of Surgeons of England, seconded by Mr E B Turner, Chairman of Representative Meetings of the British Medical Association —

> That the Central Medical War Committee and the Committee of Reference cannot continue to bear the responsibility in the eyes of the medical profession and of the community for protecting the medical needs of the civil community while meeting the requirements of the Army unless they still have the duty of deciding how many doctors and which individuals can in fact be spared at any given time from civil work in a particular place to enter military service, and that, therefore unless the War Office will undertake not to grant any commission to a doctor even though volunteering for service whom the committees consider to be for the time being indispensable for civil work the committees will be unable to take any further part in the selection of doctors for military service

Copies of the resolution were sent to the War Cabinet, the Secretary of State for War, and the Director General of the Army Medical Service

The reasons which have led the Central Medical War Committee to take this step are given at length in a statement, dated April 25th, a copy of which was sent to Lord Derby and which was issued later to the press

> In order to make the position plain the Central Medical War Committee conceives it to be its duty to the civil community to place on record a statement of the reasons which lead the Committee, in virtue of its special knowledge gained from the work it has done statutory and otherwise for the Government, to the conclusion that, unless special precautionary measures are adopted the immediate calling up of all doctors under 41 for military service affected by the War Office must inflict grave injury on the civil community in many parts of the country particularly in the industrial areas upon which so much depends both as to the production of war material and otherwise, for the carrying on of the war
>
> It is obvious that in order to avoid a breakdown in a locality, it is essential that before any doctor at present engaged in civil work is actually withdrawn from his duties the question as to whether he can at the time safely be spared from civil work must have been properly investigated to the extent required by the nature of the case either by the Central Medical War Committee, or by some other body acting on behalf of the Government possessed of the knowledge requisite for gauging the needs of the locality
>
> Hitherto the Central Medical War Committee aided by its local committees in all parts of the country and in coöperation with the Government departments concerned has performed this duty for the Government watching continuously the varying conditions of the medical services in each locality and determining from time to time in the light of those conditions how many and which doctors could be spared at any particular moment
>
> The notice issued by the Recruiting Department on Wednesday April 18th, calling up all the doctors under 41 for immediate departure on service on April 26th threw the Committee's machinery entirely out of action and, although it would seem from certain phrases in Lord Derby's letter published subsequently that some revival of the former arrangements with this Committee is contemplated, it is clear that nothing short of a Government decision to maintain the complete continuance of the requisite scrutiny will suffice to avert grave danger
>
> The following places may be mentioned as illustrating the dangers which in the absence of such scrutiny must inevitably arise in many areas:—Town *A* (chemicals and munitions) Population over 20 000. Number of doctors 4 all of military age Town and district *B* (shipbuilding) Population over 60 000 Number of doctors 10 7 of military age District *C* (coal mining) Population over 37 000. Number of doctors 7 6 of military age District *D* (agricultural area) Population (of town alone) 3628 Two doctors, both of military age. Town *E* (country town) Population over 20 000 Number of doctors 4 3 of whom are of military age Town district *F* (industrial area) Population about 126,000 Number of doctors 25 of whom 4 are of military age There is at present only one doctor to over 5000 people
>
> It is clear that from none of these areas could all the doctors liable under the Military Service Acts be withdrawn simultaneously without complete breakdown. But under the arrangements so far made in connexion with the immediate calling up of the doctors there is nothing to secure that these men will not in fact be withdrawn.
>
> Doubtless the War Office if aware of the facts, would not propose to take all the doctors from the town *A* and leave a population of 20,000 in a munition area entirely without any medical practitioners to look

after them But the War Office is not in possession of the knowledge requisite for avoiding the mistake nor is it possible for any general or mathematical rules to be formulated for such purpose The necessary safeguards can only be applied by a body which is continuously surveying the needs and the comparative conditions of the various localities

It is clear, the statement concludes, that if the situation above indicated is to be avoided, as the Government must obviously desire to secure, it must be definitely provided that no doctor, even if he himself offers no objection to going, shall be withdrawn by the War Office from the work of the civil community until the competent body authorised by the Government has ascertained and reported that his departure will not cause a breakdown

Lord Derby s Reply to the Committee

The reply received from the Secretary of State for War bearing the same date as the covering letter enclosing the Central Medical War Committee's resolution and statement was to the following effect —

War Office London S W 1 April 25th, 1917

GENTLEMEN —I am in receipt of your letter of April 25th and in answer to it I beg to state that I agree that the procedure prevailing up to last week with regard to the selection of doctors shall be continued and I will further agree not to give a commission to any doctor except on the recommendation of your Committee

Your Committee is asked to provide the Army with *x* doctors by May 1st and *y* doctors per week after that date until the requisite number *x* has been found In the event of the number so asked for not being forthcoming I must reserve to myself the right at any time to reconsider the position

I trust that this arrangement will be agreeable to your Committee and that they will continue doing the excellent work for the War Office that they have done in the past Yours faithfully

(Signed) DERBY

The Text of Lord Derby s Letter to the Medical Profession

The text of the letter addressed by the Secretary of State for War to members of the medical profession in Great Britain was as follows —

War Office London S W 1 April 21st, 1917

SIR —I am desired by the War Cabinet to ask your earnest consideration of the following matter The enemy in total disregard of the accepted tenets of civilised warfare have deliberately instituted a submarine campaign against hospital ships It has therefore become essential that a large number of hospitals should be established overseas in the various theatres of war for the treatment of the sick and wounded

In order to allow of this being done and done with great rapidity it has become essential to secure the services of every member of the medical profession who can possibly be spared from this country The figures in the possession of the Government make it plain that the number of doctors who could be spared from this country are more than are needed to supply the military requirements if adequate steps are taken by the doctors over age or by other means for doing the work in this country of the men who must now be taken for medical service overseas For these reasons the War Cabinet have decided as the first step in this process that every medical man of military age must be called up at once under the Military Service Acts in order that he may thus be made available at once, and that, if he cannot be spared from his locality without arrangements being made for carrying on his work his case may be immediately investigated and decided upon and steps taken for securing a substitute for that work

Every medical man thus summoned must therefore communicate immediately to the Central Medical War Committee (or the Scottish War Emergency Committee) if he is of opinion that circumstances (personal or public) make it impossible for him to go e.g that he can only be spared from his present duties when some arrangements have been made for doing his present work. May I express the earnest hope that every doctor over military age will immediately offer his services to the Local Medical War Committee of his area as willing to undertake any substitution work within his capacity which would help to release any man of military age who cannot otherwise be spared ?

The War Cabinet recognise to the full the great services that the medical profession has rendered during the present war and regret that the barbarous action of the enemy compels a further call on their services and a resort by the Government to measures which the Army Council had intended to avoid and could still have avoided but for this new phase of German outrage They recognise that the new procedure must involve additional sacrifices for the people of these islands and must fall heavily on the medical profession But the War Cabinet trust and believe that this call will be met in the same splendid spirit with which previous calls have been met, and that members of the medical profession and the public whom they serve will ungrudgingly make whatever sacrifices may be necessary in order that our soldiers abroad may have the same attention and care which medical science provides for their comrades at home

I am Sir your obedient servant

(Signed) DERBY

THE NATIONAL MEDICAL UNION AND MEDICAL MOBILISATION

We have received from the National Medical Union a communication signed by the chairman of the council and of the executive committee welcoming that portion of Lord Derby s letter which states his determination to call up immediately all medical practitioners of military age but objecting to non panel practitioners being asked to attend patients under the National Insurance Act The alternative is stated thus —

> While the simplest, and therefore the best means for utilising the services of the whole profession at this juncture would in our opinion, be the abrogation during the war of the Medical Benefit Section of the National Insurance Act, an emergency measure for the remuneration on non panel lines of non panel practitioners called upon to attend insured persons could we believe, be devised with the funds now at the disposal of the National Health Insurance Department It would be based upon the sound principle of payment for work actually done and would involve the allocation of no additional public money or instant disturbance of the Act.

THE WAR AND HOSPITAL SHIPS

The sinking of hospital ships by the enemy continues On April 17th the s s *Donegal* and the s s *Lanfrano* were torpedoed without warning The *Donegal* was carrying slightly wounded cases, all of them British, out of whom 29 men and 12 of the crew are missing The *Lanfrano*, in addition to 234 wounded British officers and men, carried 167 wounded Germans a medical personnel of 52 and a crew of 123 Of these, 2 wounded British officers, 11 wounded British of other ranks, 1 R A.M C staff, 5 crew, 2 wounded German officers, and 13 wounded Germans of other ranks are reported missing and presumed drowned British patrol boats rescued 152 wounded German prisoners The vessels were under escort, and one of them bore the distinctive marks laid down by the Hague Conference The Admiralty announce that in future ships carrying wounded will bear no distinctive markings, and will proceed at night without lights, inasmuch as the prescribed markings now serve only to make the ships a better target for the enemy
